For many years we have been in the habit of coating our walks over with a slight sprinkling of cockleshells obtained from the seashore. The walk, being previously formed of every conceivable substance that would act as a substitute for gravel, is last of all slightly coated over with these shells, which, if not in a broken state at the time, speedily get broken up into fragments often not larger than wheaten chaff or bran, and a comfortable path is the result, unless in places where the weeds grow and the hoe is had recourse to instead of applying salt. I may here remark that where the surface of the walk has been made of a considerable amount of fine gravel or sharp sand the hoe may be used without much harm on level ground; but on hilly walks, liable to flooding from thunder storms and the like, it is not advisable to loosen the surface to cause it to be carried to the bottom by flood water, and in that case salt had better be applied. Now I have heard a good deal said against salt and not a little in its favour, and both may be right to a certain extent; but I confess being an advocate for salt in all cases where the foundation of the walk is of a moderately porous character, but the continued use of salt has a tendency to destroy that porosity. My object, however, is not to show what evils salt may now and then do in the way of soddening a walk, but to point out an instance where it has brought a certain plant of its own with it, and this, too, in the shape of a weed not met with formerly on the spot.

The plant I have to complain of is, I believe, an *Arenaria*—a low-growing spreading plant, the seeds of which doubtless have been imported with the shells, and being a seashore plant it seems to glory in and relish the doses of salt given the walk to destroy the natural weeds of the place, and it occupies a site where it is not advisable to employ the hoe; and I should like to know if any other of your readers have been troubled with it who have shell-covered walks and depend on salting more or less as a means of destroying the weeds. We have not been troubled with it in many places, but where it does find its abode it seems very tenacious of life. I daresay hot water or some poisonous substance would kill it, but I have an aversion to the latter substance, and we are rather too far distant from a building to get hot water handy. Other noxious weeds are destroyed, but in most places there are spots not much trodden on by pedestrians, and it is in such places this pest fixes itself, insidiously spreading itself along the ground; and though not more than 2 inches high is very dense, and its small pale rose-coloured flowers are not without their beauties to the botanists and others, while to the gardener the plant shows itself where it is least wished for, and no doubt others as well as myself would like to know how to expel it by some easy process that would neither disturb the walk nor incur much trouble of another kind. I may at the same time remark that in absolute wear it is nothing like so tenacious of life as Bearbind and many other kinds of weeds, but it is nevertheless a nuisance that it would be better to be rid of, and a ready way to do it will be acceptable; while at the same time it would be well to ask if it is met with elsewhere on walks that have had a covering of sea shells given them.—J. ROBSON.

#### THE LATE REV. WILLIAM HICKEY, M.A.

In our last issue we merely communicated to our readers the intelligence that death had snatched this just and distinguished man from among us. We now proceed to give a few particulars of his useful, retiring, but not undistinguished career. On Sunday the 17th October he performed Divine service in Mulrankin church with his usual vigour. On Friday he felt slightly indisposed, and gradually sank, suffering no pain whatever, until the following Sunday, when he resigned his spirit into the hands of his Divine Master, at the patriarchal age of eighty-eight. His whole course of action has been associated with the state and progress of Ireland during the last fifty years, and many of the schemes propounded by him for the benefit of its people—at one time, perhaps, considered utopian—have since been practically and beneficially realised. He was the eldest son of the Rev. A. Hickey, D.D., rector of Maragh, county Cork; was scholar of St. John's College, Cambridge, where he graduated as A.B., and subsequently took the degree of M.A. in Trinity College, Dublin.

He was ordained in 1811, and appointed to Dunleekney, diocese of Leighlin; became rector of Bannow, in the diocese of Ferns, in 1820; rector of Kilcormusk in 1826; rector of Wexford in 1832, from which he was promoted to the parish of Mulrankin in 1834. Previous to his departure from this town for the new sphere of his spiritual duties an address was presented to him signed by all sects and parties—the late William Whitty, who had been selected the first Catholic Mayor since the Reformation, heading the list, followed by upwards of 130 names. The address was presented by the late Dr. Renwick (Hon. Secretary) in these words:—"It has happily fallen to my lot to be the medium of conveying to you the accompanying address, signed with an unanimity that has never been exceeded, if indeed it has ever been equalled, in any community composed like ours of Protestants, Roman Catholics, and Dissenters. Looking at the state of society in this divided country, never was a higher compliment paid to the character of any individual than this truly representative address embodied; and never was the sentiment *exegi monumentum ære perennius* more faithfully exemplified than in this instance." Therefore we need not add that as a parochial clergyman he was highly valued by his flock; and in his public ministrations, both as reader and preacher, his capabilities were acknowledged to be of the highest order. As a writer he early commenced to advocate the improvement and social progress of his fellow countrymen. So far back as the year 1817 he published a pamphlet on "The State of the Poor in Ireland." Afterwards appeared several letters from his pen under the *nom de plume* of "Martin Doyle," by which name he has been so generally recognised as an author. "Hints to Small Farmers" succeeded those of "Martin Doyle," and were read with deep interest, and the sequel proved with signal advantage, by those for whose welfare they were written. They were followed in rapid succession by the subjoined well-known works:—

"The Hurlers," "Common Sense for Common People," "Irish Cottagers," "Plea for Small Farmers," "Address to Landlords," "The Kitchen Garden," "The Flower Garden," "The Illustrated Book on Domestic Poultry," "Hints on Gardening," "Hints to Small Holders on Planting, Cattle, Poultry, Agricultural Implements and Flax," "Hints on Emigration to Canada," "Hints on Health, Temperance, and Morals," "Book on Proverbs," "The Village Lesson Book," "Cyclopædia of Practical Husbandry," "The Labouring Classes in Ireland; an Inquiry as to what beneficial changes may be effected in their condition."

He also translated from the French "Sermons by Monod," and for a length of time was a regular contributor to "Blackwood's Journal of Agriculture," "Chambers's Journal," and to various other periodicals of the day. In all these publications he took the broadest philanthropic views, studiously avoiding religious and political controversy. His latest production was "Notes and Gleanings of the County of Wexford," a work abounding with statistical facts and information. In conjunction with the late Thomas Boyce of Bannow he started the South Wexford Agricultural Society, and founded the Bannow Agricultural School, which was the first of the kind established in Ireland. He was a member of the Royal Dublin Society, and was awarded their gold medal in recognition of the services rendered to Ireland by his teachings; and Government in granting him a pension from "The Literary Fund" only endorsed the universal sentiment of the empire. For many years he held the commission of the peace for the county Wexford, and no man ever discharged its functions with more fidelity. He died comparatively poor; for, throughout a lengthened span not accorded to many he invariably denied himself that he might be the better able to assist others, and in this lies his most effective and unfading eulogy.—(*Wexford Independent*.)

#### NOTES ON VILLA AND SUBURBAN GARDENING.

ASPARAGUS, SPINACH, AND RHUBARB.—With these the forcing season may be said to commence, and I would say that there are few things, if any, that can be artificially brought into use with so little expense. A little trouble there must be, but that must be thought little of in comparing the success that is likely to attend the efforts to obtain the luxury of a few early dishes of these delicacies at the most unseasonable time of the year. It should be remembered that those who regularly practise the system of forcing these vegetables pay much attention to the proper growth of the stools the year or more previously; because if the crowns are properly developed, and have well ripened off,

the produce will be greater accordingly. The above conditions being duly provided, all that is necessary is the application of sufficient heat to start the crowns into growth. They are not particular as to the place or how they are forced—whether it be by a mixture of dung and leaves covered over pots on the outdoor bed, or by the same heating medium applied to a frame, and the roots taken up carefully from the ground and planted compactly in a bed of soil, or by hot-water pipes in a regularly heated house. By any plan the Seakale must be kept in the dark in order to blanch it properly for the table, but both Rhubarb and Asparagus have a better flavour if light is admitted: this gives them more of their natural colour.

With the exception of Asparagus, which I generally force in a frame, the other two are taken up and put into a room where we generally grow our Mushrooms; not a regular Mushroom house, but the heat is kept up by a heap of dung and leaves thrown up in the middle of the room and refreshed as often as required. There is no difficulty in keeping the heat up to 60° all through the winter, which is quite high enough for Mushrooms, and allows the Seakale and Rhubarb to come on steadily for a fair produce. It will be seen that three important crops are going on at one time, and it is done with a small consumption of heating material, which I am compelled to make the most of. When grown in this way there is little danger of overheating, but in a frame the sudden changes from mild weather to cold cause more heat to be applied; and when it as suddenly changes the reverse way there is a danger of extreme heat, so injurious to these things. The principal points to aim at are a mild bottom heat and very regular, and the heated atmosphere quite as regular in the house, room, or frame, as the case may be. With manure the atmosphere will be sure to be moist enough, or with hot-water pipes it may be necessary to apply a little water occasionally both at the roots as well as on the floor of the house.

In the month of December, when Endive is becoming scarce, some roots of Chicory are forced by the same means and planted in the same manner, and blanched the same way as for Seakale, and there is a regular crop of salads and choice vegetables grown in one room.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR - THE PRESENT WEEK.

### KITCHEN GARDEN.

This is the month that any alterations in the garden should be carried out, and all vacant ground be dug or trenched, but lately rain has been so prevalent as almost to render digging impracticable. Trenching is a very important operation in the kitchen garden. A certain portion of ground should be trenched over annually, and when manure can easily be obtained a layer should always be put into the bottom of the trenches. Nearly all kinds of soil are improved by being trenched, but there can be no rule laid down as to depth, which must be left to the intelligence of the gardener. It is not well, however, to trench ground very deep that has not been moved more than a spit for a generation or more. In a case of this kind we generally work the ground two spits deep, and the following season take two more spits, but shovelling the loose earth out after each. This leaves a hard bottom, but a man with a fork digs this bottom over, loosening it to the depth of say 9 inches, but not turning the subsoil over. Although manure is very expensive here, we use a large quantity upon ground trenched in this manner for most vegetable crops. Peas especially are immensely benefited by the manure being placed at the bottom of the trenches. Our plan is to put in two layers of manure, one at the bottom and the other after a spit and the loose earth has been thrown over it. Working the ground in this way will cause it to produce such a crop in dry seasons as it would not otherwise produce without abundant supplies of water. Some gardens have the water laid on, and an abundant supply is always at hand; but these are highly favoured, and as yet are the exception. Where water has to be carried or carted a considerable distance at a time when work is pressing, it does not require much calculation to see that if this labour can be saved by deep trenching and manuring in autumn and winter the time and money ought to be given at the right time.

This is also a good time for relaying the Box edgings if such work is necessary. Blanks are made in the edgings from various causes. Sometimes the soil is unsuitable, at others the crops spread over the edging, which is a fruitful source of decay. A little good can be done by filling up the gaps with fresh Box, but occasionally it is necessary to replant the whole. The work must not be hurried over, for it is intended to last for many years; and if the lines are crooked where they ought to be straight, or the ground is not level where it ought to be, the edgings will be a constant eyesore. First the gravel is cleared off from the sides into the middle of the path; the Box is then lifted and laid in until the ground is ready. The ground must be dug up, and in doing so the soil that has grown the Box should be

thrown on to the border, and fresh material be returned from the border to supply its place. The ground ought to be trodden down firmly with the feet, and be made quite level by beating it with a spade after raking it previously to planting, and the line that the Box is planted by must be drawn quite tight before the space for the Box is marked off with the spade. The stalks of Asparagus have been cut over, and the beds will be dressed with manure when the ground is harder and more adapted for wheeling upon.

### PEACH HOUSES.

The trees must now be made ready for forcing, if an early crop is desired. When writing on this subject in previous numbers we have always recommended keeping the inside border moderately moist even at this dull period of the year and when the trees are at rest. The same attention is required here as in the vineries; for the Peach has quite as many enemies as the Vine, if not more: aphids, thrips, spider, brown and white scale lodge in the branches of Peach trees at this season. If scale is present it ought to be removed before washing the branches with the same mixture recommended to be used in the vineries. If the inside border has become very dry it ought to be watered at once, but the house should not be shut up until a week or so after; still there is not much danger when the blossom buds are not very far advanced. When Peaches are forced early the utmost care is necessary to keep the roots as well as the branches in a healthy condition. Anything that might check growth would cause the blossoms to drop off at or before the time of setting. When the house is started the temperature must be very low at first, merely shutting up early in the afternoon, and keeping the ventilators a little close. When fire heat is applied it must be with caution.

### MUSHROOM HOUSE.

This is a bad time for collecting material for the beds, as the continued damp atmosphere prevents the manure from drying; but if it is spread out in an airy shed and turned over daily the moisture will be thrown off when the weather is favourable. The late Mr. Fish recommended dry litter or straw to be cut up and mixed with the manure when it was very short and damp. We never tried this plan, but it would no doubt answer very well, and sufficient heat could be obtained from it. The whole would have to be thrown together in a heap to ferment and to throw off the rank steam. If beds in bearing become dry they must be watered, after a gathering has been made, with water about 85°; the water should be applied through a fine rose gently, so that it may soak into the beds equally, instead of running off and down the sides. Woodlice are very troublesome when the bed shrinks from its becoming dry; they find an excellent harbour between the wall and the dry manure. Boiling water may be poured down the fissure, which will destroy them; or if they cannot be reached in this way, a few boiled potatoes wrapped up in dry hay and laid upon the surface of the beds will attract them in large numbers, when they can be shaken out from the hay and destroyed. If a bed should lose heat before the Mushrooms appear some dry straw or hay may be laid on the surface; this will retain heat and moisture, and frequently causes a crop to appear which might otherwise have failed; the crop will also be produced a few days earlier.

*Seakale and Rhubarb.*—A few pots of Seakale may now be removed to the Mushroom house. It will be necessary either to invert a pot over each, or else place the pots where the Seakale will be in a dark place. Rhubarb does not require so much attention, the roots are merely lifted and placed together on the floor of the house. The roots of both must be kept sufficiently moist.

### CUCUMBER HOUSE.

A large number of Cucumbers are not required from our house, and we do not hurry the plants; 65° at night or 60° is our average temperature. If the weather should be severe we would rather let the temperature fall to the lowest figure than over-heat the pipes to raise the temperature if it had fallen. A very moist atmosphere at this season is not desirable, for it causes a watery growth and thin leaves, which will not resist the effects of cold and dull weather.—J. DOUGLAS.

## TRADE CATALOGUES RECEIVED.

John Harrison, North of England Rose Nurseries, Darlington.—*Catalogue of Select Roses.*

Messrs. Toole & Co., 22, D'Olier Street, Dublin, and The Nurseries, Cullenswood, Ranelagh.—*Catalogue of Forest and Ornamental Trees, Evergreens, Roses, &c.*

Francis & Arthur Dickson & Sons, 106, Eastgate Street, and the "Upton" Nurseries, Chester.—*Catalogue of Roses and Decorative Plants.*

## TO CORRESPONDENTS.

Books (*A Subscriber*).—Your query is very vague. "The Botanical Magazine," published monthly, has coloured engravings of flowers, &c. (X. O.).—Our "Vine Manual." You can have it free by post if you enclose thirty-two postage stamps with your address.

**HORTICULTURAL CHARADES (Annie).—**We know of many superior to yours. For example: If two flowers could marry, which would they be? Jon-quill to Mari-gold. There is also the apothegm, If you desire Hearts-ease do not endeavour to marry-gold.

**Pronunciation of TROPÆOLUM (Polly).—**The accent ought to be on the diphthong.

**GRASS-GROWING (J. Greenaway).—**Our native species will grow at any temperature above the freezing point of water.

**PRIZES FOR ROSES (A Young Beginner).—**We quite agree with you that nurserymen and amateurs ought not to be compelled to exhibit in the same classes. Neither are they so compelled, for in all properly arranged classes there are open classes also—classes for nurserymen and classes for amateurs.

**NOTICE OF INTENTION TO LEAVE (Inquirer).—**A week's notice to an employer is sufficient from a weekly-paid servant.

**PRUNING AUTUMN-FRUITING RASPBERRIES (Clara).—**They do not usually bear good fruit on last year's canes, or if they do it is in July like our summer-fruited sorts, and the yield in autumn is but small. It is good practice, as advised by Mr. Rivers, to cut down all the canes close to the ground in February, and in May pull up all but three or four of the strongest, leaving them about 1 foot apart. Except in the south, and warm sheltered situations in the midland and northern counties, they do not always ripen their fruit well in autumn.

**COALS (J. H.).—**We cannot give the analysis of the different varieties. "Cannel" and "Scotch Cannel" are not the same. Cannel coal will not heat water so rapidly as caking coal. If you have any kind of coal near you we advise you to use it; the cost of carriage from a distance would exceed any superiority in a coal's heating power.

**ROSE-GROWING (Monte Christo).—**We cannot tell the best locality near London. Anywhere if the soil is a rich loam and the subsoil not chalk.

**AN OVAL BED.—**A ready way of forming a bed of this agreeable shape is to place two pegs in the ground at any given distance apart (say for example 8 feet), and then take a piece of twine 7 feet long and join the ends; place this hoop of string over the pegs, and then with a nail or stick, as though you were describing a circle, keep the twine extended round both pegs, and your oval is complete. The size or the shape of the oval can be regulated by moving the pegs closer to or farther from each other.—B. H.

**TEMPERATURE OF CONSERVATORY AND DRAWING-ROOM (J. R. W.).—**"A lady wishes the conservatory to be kept as warm as her drawing-room; the gardener states that that would be injurious to the plants." We know one lady who will not tolerate a temperature below 60° in her drawing-room, and another who cannot endure it to exceed 50°. Suppose we take the mean of these figures—55°, which is alike healthy and comfortable; then we say, provided there are no permanent plants in the structure such as Camellias planted out, that there are a sufficient number of decorative plants which would not only endure that temperature but which would enjoy it. If it is too cold to be comfortable for a lady we advise that it be made warmer, and that a class of plants be employed which will be suitable to the temperature required. We put it at 55°. Now, that is a temperature which will admit of being placed in the conservatory many attractive plants. Poinsettias, Gesneras, many Orchids, Epiphyllums, Eucharisas, Begonias, with such ornamental-foliaged plants as Palms, Colusenas, even Dracenas, and most of the choice Ferns may all be placed in structure, having for its minimum the temperature above named. Furthermore, the same temperature will be endurable by Cyclamens, Mignonettes, Primulas, and Cinerarias, only they would not last so long in beauty as in a cooler house, and larger stocks would require to be grown. The same remark applies to Roses, Azaleas, Deutzias, Spiræas, and almost all winter and spring-flowering plants, and we are not certain that it would really injure Camellias in pots, but if planted-out we should consider it too exciting, and if a house had been kept cold and was suddenly raised 10° or 15° there would be danger of the buds dropping.

**VINES FOR GLAZED VERANDA (W. C. F.).—**There is no saying how many Vines you will have accommodation for, as you say the house is 40 to 50 feet long. We will take it at the latter, which will give you room for Vine rods at 4 feet distances, and we should train each Vine with two rods, planting from each end 4 feet, and the Vines afterwards 8 feet apart. We should cut each Vine back to a foot of its base, and when the eyes break select two shoots of equal strength, and train to the right and left respectively for 3 feet, and then upright, and up to the top of the roof. You will require six Vines, and these may be two Black Hamburgh, one Trentham Black, one Duke of Buccleugh, one Foster's Seedling, and one Buckland Sweetwater. Plant in spring, when the Vines are beginning to grow.

**TRANSPLANTING MANETTI STOCKS—BRIARS AND ROSES (St. Edmund).—**Transplant now or early in December, and plant firmly. The Briar stocks require no preparation, only to be cut with about 4 to 6 inches of root stem, and planted at once in good rich rather strong soil. Now is a preferable time to plant Roses than spring. The buds recently started into growth will, should we have severe weather, from their unripe growth be liable to suffer, but you may protect them by a little dry hay wrapped lightly around them, removing in mild weather.

**RAISING BRIAR STOCKS FROM SEED (R. B.).—**Sow the seed now, or you may keep the heaps in sand until spring, and now, or then, dividing the heaps into as many parts as there are divisions sow in drills about an inch deep and 6 inches apart, and cover with fine soil. The seeds should be sown about an inch apart. Some of the plants will come up the first year, but a majority not until the second, taking-up the growth of each year in autumn after the leaves have fallen, planting 6 inches apart in rows 2 feet apart, and the following season many if not all will be fit for budding as dwarfs.

**TREES IN ORCHARD HOUSE (Inquirer).—**We should prune the trees as soon as the leaves have fallen, and as the trees are planted out remove the surface soil without disturbing the roots, giving a top-dressing 2 or 3 inches thick of equal parts of turfy loam and rotten dung, making it firm. Remove the Vines if they are likely to shade the trees. "Hints on Orchard Houses" may be useful to you. It may be had free by post from our office for 2s. 7½d.

**PEAR AND APPLE TREES UNFRUITFUL (Idem).—**The soil is evidently poor. Burning the clay and mixing it with the soil with a liberal dressing of manure would improve it. Mulching around the trees as far as the roots extend with short half-rotten manure would attract the roots to the surface, and the trees would be more healthful and fruitful.

**ERRATUM.—**In the article on Clapp's Favourite Pear, on p. 397, second paragraph, for "last year" read "last used," my object being to show the continuance in season of the kinds named, and not the ripening of last year.—G. A.

**KEEPING FRUIT (Mechanic).—**It may be true that the old gardeners took prizes for two years and for three years with the same Apples, their mode of preserving them being among dried and in air-tight jars covered with bladder, but the judges could not have tasted the fruits.

**DWARF ROSES IN GREENHOUSE (A Sub.).—**We should not advise you to plant so close as you intended; 18 inches is much too near for Rose trees. In a border 32 feet long and 10½ wide we should not recommend more than ten, or at the outside twelve, in the length, and three, or if both sides are quite free, possibly four rows in width, but 8 feet is generally better than 2½ feet. We should recommend all on Manetti, planting twelve sorts, two and two, in the two back rows, and twelve kinds of Teas in the front row. This would give thirty-six trees—i.e., three rows of twelve each, planted first Teas 2 feet from edge of border, then two rows of Hybrid Perpetuals, the last being 2½ from the vinery. Varieties—Hybrid Perpetuals: Charles Lefebvre, John Hopper, Alfred Colomb, Marie Baumann, Marquise de Castellane, Marguerite de St. Amand, Princess Mary of Cambridge, Victor Verdier, Countess of Oxford, La France, Baroness Rothschild, Boule de Neige, to which you may add Dupuy-Jamain, Emilie Hansburg, Mdlle. Eugénie Verdier, Dr. Andry. Teas: Madame Willermos, Souvenir d'un Ami, Adam; Gloire de Dijon, La Belle Lyonnaise, Céline Forestier (Noisettes)—these three are strong growers; Catherine Mermet, Madame de Vitry, Cheshunt Hybrid, Souvenir d'Elise, Madame Bravy, Marie Slaley, and for a wall Maréchal Niel.

**DEFECT IN HEATING (L. F. G.).—**We fail to detect any defect in the arrangement of the flow and return pipes, and as you complain of an insufficiency of heat we conclude you have too little piping, necessitating the driving of the fire, and causing much of the heat to pass away by the chimney. Not knowing the size of the houses and the quantity of piping we are unable to arrive at an opinion.

**WINTERING FUCHSIAS (L. H.).—**They will not pass the winter safely in a cold frame unless covered with straw or other protective material, so as to exclude frost. They require to be kept dry, but not so as to cause the wood to shrivel, and if in a temperature of from 40° to 85° all the better; they will endure 45° without being unduly excited into growth.

**HIPPASTRUM RETICULATA STRIATIPOLIA TRIBUTUM (G. Diss).—**The offset sent us is of the above, and is very pretty were it only from the clear white band in the centre of each leaf, but it has in addition rose-coloured flowers with white network, which are produced in early summer. The plant ought now to be kept on a shelf near the glass, and without water or only so much as to keep the leaves from flagging, and this should be continued until it again commences to grow, when water should be given more freely, and copiously when in free growth both at the roots and overhead, continuing it until the growth is complete, and then reduce it, placing the plant in a light position, giving water only to keep from flagging, but not drying-off. Potting is best done when the plant is in free growth, and keeping under rather than overpotting, being careful not to injure the roots. It is a stove plant.

**REPORTING AZALEAS AND RHODODENDRONS (A Subscriber).—**The plants being intended for forcing ought not to be repotted until they have flowered. The most likely cause of the leaves falling is want of water, the check having been given some time ago, rather than a few degrees of frost, though that would be sufficient to induce their falling. Hydrangeas, Myrtles, and Oytiums may, if kept dry and the pots protected from frost so that the roots are not affected by it, be wintered in a greenhouse without fire heat, but they are better kept in a house from which frost is excluded, for in very severe weather the plants often suffer and are sometimes killed.

**POINSETTIAS LOSING THEIR LEAVES (A Constant Reader).—**The plants being allowed to become very dry at the beginning of September, and also being old, we are not surprised at their losing the old leaves, which old plants usually do. They do not at any time require heavy watering, only to be kept regularly moist, with a moderately moist well-ventilated atmosphere. The temperature (50°–70°), is rather high, 5° less would be better. The loss of roots we should attribute to the keeping of the plants dry and the subsequent moisture. All peat soil is not good. Good fibrous loam three parts, one part old cow dung, and a part leaf soil or sandy peat, and a sixth of silver sand is a preferable compost.

**TRAINING WALL PEAR TREES (Kitty).—**Nothing is more easy than to train wall trees on what is termed by gardeners the horizontal system, but the foundation must be laid when the trees are young. To make a handsome specimen of your tree it ought to be cut down to within 18 inches of the ground, and the two side branches should be cut back to the bifurcation. If you do not like to cut it down, then the branches marked a and b must be raised higher, allowing about 9 inches between the lowest pair and those above. c must be brought down to c, and be cut back to 6 inches. f and d must also be brought opposite each other, and the leading growth to be cut back to 9 inches. As soon as one pair of branches is formed the leader must either be cut or stopped at 9 inches above them, so that another pair may be formed, and this is carried on until the wall is covered; if any side branches (as some have done on your tree), should grow too strong for the others they must be stopped.

**APRIS ON FRUIT TREES (L. I. K.).—**The trees being unnailed from the wall, leafless and pruned, dress the trees with a composition formed of 8 ora. of soft soap thoroughly dissolved in a gallon of tobacco juice, and with this thoroughly apply to every part with a brush, reaching wall into every crack, angle, and crevice, taking care not to dislocate the buds. In case you allude to "fungus" the trees may be infected with mildew, in which case add to the above-named compound of soft soap and tobacco juice, sulphur and soot in equal proportions, so as to form a composition of the consistency of paint, and apply with a brush. We know of no "new remedy" for the Powdery disease to be applied at the time of planting, and have no faith in such nostrums. The long Pear is Van Mons Leon Leclerc; the round green one Susette de D'Avay. The two long green Pears we not know.

**INSECTS ON GERANIUMS (E. M. P.).—**We do not think you have red spider at all. If you have it upon such plants as Geraniums in a greenhouse it will soon disappear with syringing every morning with water only. It is more likely to be thrips, and those you may destroy by fumigation with tobacco, selecting a calm evening for the operation, having the foliage of the plants dry, and with the house shut-up close, filling it with tobacco smoke so that a plant cannot be seen from the outside through the glass. Do not remove the plants and burn sulphur in the house, but send us a leaf or two infested with the insects, and we may probably tell you what they are and what remedy to apply.

**PINE PLANTS INFESTED WITH WHITE SCALE (A Constant Reader).—**Take of tobacco juice a gallon, and in this dissolve 1 lb. of soft soap and 1 lb. of gum arabic, adding when thoroughly dissolved a wineglassful of

sprits of turpentine, and apply the mixture with a brush to the leaves and every part infested, having the liquid well stirred and mixed, and applied at a temperature of 130° to 180°, and this will remove or smother the scale, and after twelve hours the plants should be thoroughly syringed with clean water also at a temperature of 130° to 180°. If the scale infests the base of the leaves it is best to place the plants infested in a frame over a bed of hot dung, the frame being full of vapour from the hot dung, and the heat not exceeding 100°; and the plants placed therein for twelve hours and matted over, and upon their removal from the frame syringed with a solution of soft soap 4 cwt. to a gallon of water, applied at a temperature of 130°, the plants will in all probability be cleared of the pest, or it may be necessary to repeat the treatment. Any bed of hot dung in readiness for Cucumbers, &c., before the soil is put on the bed, the bed being made up of sweetened dung, will answer, and as yews are suckers it may be the readiest mode for you to adopt.

**TEMPERATURE FOR PLANTS IN WINTER (Donna Serafina).**—You ask us to give the culture of no less than seven species of as many genera. Our reply must be brief. *Bromelia carolina* is to be kept dry, but not so dry as to cause the leaves to become limp; *Dioscorea Walpoleana* requires to be kept moist, and to have gentle sprinklings overhead twice daily; *Eucharis amazonica* to be kept dry, the leaves not, however, allowed to flag, and in January potted and encouraged with a brisk heat and moist atmosphere; *Alocasia metallica* to have the treatment of *Dioscorea Walpoleana*; *Sinclairia nobilis* to have water to maintain the foliage fresh; *Ixora coccinea* to have water to keep the foliage from becoming limp; and *Allamanda* to be kept dry, but the wood not allowed to shrivel. A temperature of 65° to 60° by night with a decline in very severe weather to 55° in the morning, 65° to 70° by day from fire heat, and 75° to 80° or more with sun and air. The Gesnera is probably *Dioscorea*, and the leaf may be an *Eranthemum*, but from a leaf and that one discoloured it is not easy to determine the name.

**COMPOST FOR MELONS (G. G.).**—The top 8 inches of a pasture taken off with its turf and laid-up in a ridge-like heap, with a layer between each layer of turf of fresh cow dung an inch thick, and this allowed to lie six months, and then chopped-up and thoroughly mixed, is the soil from whence the turf is taken being a strong or clayey loam, the best possible compost for Melons, it being put in firmly a foot deep.

**AQUATICS IN VIKERY (T. B.).**—Aquatics require light not shaded positions, and will not do well if the roof be closely covered with the foliage of the Vines, but if only moderately shaded they may be fairly successful with *Aponogon distachyon*, *Dicella bicolor*, *Houttuia cordata*, *Limnorchis Plumieri*, *Nymphaea thermalis* (Lotus), and *N. odorata*.

**POTTING AND PRUNING ROSES (T. B.).**—Report them at once, removing all the soil that can be done without injury to the roots, giving a moderate shift, employing a compost of three parts well-reduced turfy loam with a fourth part of old cow dung or well-rotted manure. Teas require rather lighter soil than *Perpetuals*, affording good drainage. After potting place the plants in a cold pit or other position where they can be protected in severe weather, the pots plunged in ashes to the rim, and prune the plants when they are taken into the house, which if a greenhouse for Roses in April and May will be the early part of January. The Teas require very moderate pruning, and the *Perpetuals* rather close pruning.

**UNBINDING ROSE BUDS (E. S.).**—The ligatures ought to have been slackened in about a month after putting-in the buds; unfasten them now, and let them remain loosely bound over the winter, removing the ties when the buds are growing. There is nothing to hinder your having standards or half-standards, but on the seedling as well as *Briar* from cuttings dwarfs are preferable. The Apple is not known to us by the name you received it.

**ORCHIDS IN CUCUMBER HOUSE (Richard Perrey).**—The house will be suitable in winter for some of the warmer-temperature-requiring kinds, but as you have no heat after April except a warm greenhouse we do not consider you would succeed with them at that season, they requiring more heat and moisture during the summer than winter months. We should not advise your attempting their culture unless you can give them more heat in summer than a warm greenhouse. Our "Orchid Manual" would suit you. It may be had free by post from our office for thirty-two penny postage stamps.

**RHUBARB FORCING (Mary, Dublin).**—To plant Rhubarb in a grassy run for fowls, and cover with earthenware pots, surrounding them with hot dung at 2s. 6d. a barrowload, is a most extravagant way of forcing Rhubarb. You may plant Rhubarb roots in the grass run, manuring the soil liberally, and planting so that the crowns are slightly raised above the surrounding level, covering them 2 or 3 inches deep with rich light soil, and over each crown you may place the pots, and cover over as well as surrounding with hot dung, which will give you stalks fit for use in about three weeks, or if surrounded and covered with litter you will have Rhubarb three weeks or so earlier than were it uncovered.

**TUBULAR BOILER (G. Y. E.).**—The boiler as shown in your sketch must be set upright, the one outlet—i.e., flow at top, and the two at the base will be return. Your object in setting horizontally is no doubt to save a deep stovehole, but that you must submit to with the present boiler. You will have more heat with the boiler set perpendicularly than horizontally, which would not work satisfactorily nor save anything in fuel. We are unable to see that you will have more heat in the propagating houses than in the other two compartments, which in addition to the pipes for bottom heat should have twice the quantity for top heat as the other, which may be effected by a branch pipe on both the flow and return as the pipes pass through the propagating house, they being double in it but single in the other two, as shown in your sketch, which will be sufficient for Roses and greenhouse plants. We should, however, have a flow and return into the propagating house in addition to those shown, and these represented by you we should have a valve upon in the propagating house, so that the heat can be shut off from the Rose and plant house at will, with a flow and return always on for the propagating house. The conservatory should have three rows of 4-inch pipes the length of the house, and they ought to be in front, or if you have them in the path in a fine covered with iron grating four rows will be necessary. In the pathway would appear the best arrangement for the pipes as you have borders with plants in them. You will need valves upon the flow and return pipes of the conservatory, and where the pipes branch from the boiler for it. The nearer to it the better, so that you may not have any waste of heat in uselessly heated piping.

**HYBRIDISING (A Pomologist).**—There are full details in the second volume of McIntosh's "Book of the Garden."

**ERRATUM.**—The collection of vegetables for which Messrs. Carter & Co. were awarded a silver medal at South Kensington last week, was described as containing "eight" sorts of Potatoes, it should have been eighty varieties.

**BULBS IN WINDOW BOXES (Novice).**—You may place the pots in the window boxes, the pots being plunged over the rims in the soil or in coco-nut refuse, and they will survive the winter; but they would be better plunged in ashes in a sheltered spot until February, and then placed in the boxes. The Crocuses planted now will flower in March, the Hyacinths in April, and Tulips in May.

**GRAFTING PEARS ON QUINCE STOCKS (C. P. Q.).**—The most eligible mode is tongue or whip grafting. The scions of Pear, Plum, and Cherry should be taken off in January, and their lower ends be placed in moist soil. The stock should also be headed back then to nearly where it is to be grafted, leaving however a little of the stocks to be cut off at the time of grafting. The grafting should be done in March or when the stocks are starting into growth. In taking the scions of Plum and Cherry make sure that they have wood buds, otherwise they will not grow.

**STRIKING WITH SOFT SOAP SOLUTIONS (J. H. D.).**—The soft soap solution coming in contact with the soil and absorbed, will not, except in excessive quantity, injure the roots of the plants growing in it. It would be better kept from the soil of pot plants, which may be effected by laying the plants on their sides, and turning round so as to wet every part with the soap solution, washing the pots afterwards, as the soapy water adheres to them and has a very unsightly appearance.

**NAMES OF FRUITS (Englemer).**—2, *Bourré Clairgean*; 3, *Van Mons Léon Leclerc*; 4, *Vicar of Winkfield*; 5, *Huysh's Prince of Wales*; 6, *Ne Plus Meuris*; 9, *Eyewood*. (*Connaught Subscriber*).—Apples: 1, *Scarlet Pearmain*; 2, *Striped Beaufort*; 8, not known. *Pears*: 1, not known; 2, *Easter Bourré*; 3, *Bourré Bosc*. (*A Constant Reader*).—3, *Doyenné Boussoch*; 6, *Bourré d'Anjou*; 12, *Soldat Esperen*. (*E. H. R.*).—The large yellow one is *Bourré Dial*, and the small one *Gansel's Bergamot*. (*J. M. J. D.*).—*Pears*: 1, *Nouveau Potteau*; 2, *Zéphirin Grégoire*; 3, *Brown Bourré*. *Apples*: 4, *Tower of Glamis*; 6, *Boston Basset*. (*Henry Turnbull*).—1, *Forale*; 2, *rotten*; 3, *Marchal de Cour*. (*W. G.*).—No. 1 is a good Apple, but has nothing remarkable in its flavour; 2, *Mère de Ménage*; 3, *Emperor Alexander*. (*C. Z.*).—No. 2, *Bourré Sterckmans*; 6, *Bourré d'Arnhemberg*; 8, *Vicar of Winkfield*; 15, *Colmar d'Arnhemberg*; 14, *Bergamotte Esperen*; 12, *Doyenné Goubault*. (*C. Turner*).—*Herefordshire Pearmain*. (*Davie Drake*).—1 and 2, not known. 3, *Court of Wink*. (*J. Kelway*).—A showy Apple of no special merit; probably a seedling from a *Sider Apple*. (*T. Holman*).—*Nouveau Potteau*.

**NAMES OF PLANTS (W. T. C.).**—1, *Nephrodium (Lastrea) dilatatum*; 2, *Aspidium angulare*; 3, *Cystopteris fragilis*; 4, *Aspidium aculeatum*; 5, *Adiantum hispidulum*; 6, *Adiantum Capillus-Veneris*. (*H. Grayson*).—*Davallia canariensis* and *Polypodium Billardieri*. (*J. L. C.*).—*Felisia falcata*; 2, *Felisia rotundifolia*. (*Somerset*).—1, *Polypodium Dryopteris*. 2, *Aspidium angulare*. The other three seem all forms of *Adiantum canescens*. (*E. V. K.*).—It appears to be a species of *Kalanchoe*. (*M. A.*).—1, *Saponaria officinalis*; 2, *Tradescantia virginica*. It is difficult to determine species of *Aster* except from very good specimens; 4 is probably *A. Novae-Angliae*. (*G. M.*).—*Escalonia rubra*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### CRYSTAL PALACE POULTRY SHOW.

THE grand national poultry Show for another year has come and gone, and this evening the Crystal Palace Meeting of 1875 will be a thing of the past. Everyone looks forward to this gathering, and while the *menu* presented continues so choice, and the servers themselves so courteous, nothing else will be able to get into the running as a national show. It is true this year the numbers of entries are less, but that is nothing, for all the while we find four thousand pens we shall be satisfied that this Society is doing good work and producing good fruits. To account for the lesser number of entries this time we have the unsuccessful months of the early year, when in many places the chickens refused to leave the eggs; and then we have the Alexandra Meeting, which for the first time held its levée this season, and doubtless birds which were found to be quite out of it there were not entered here. As we should imagine, some did not post their entries until the state of the Alexandra poll was declared. Lots of good birds make their *début* here. One or two of our greatest breeders have not exhibited before this season, waiting for this meeting; and we are not disappointed with the results, for we have friends among the little birds, and they come to us with tiny whispers of what Mr. A. has, or how Mr. B.'s birds are moulting, or that Mr. C. has some young wonder in store for the tournament. We may say of the poultry world very truly, that

"Moving through a mirror clear,  
That hangs before her all the year,  
Shadows of the world appear."

for it is wonderful to notice how much truth there is in these shadows that from time to time flit across our paths from the large establishments. Of course, lots of recent decisions are turned upside down here. The winning heroes and heroines of former shows have here to put up with those horrible "highly commended," horrible because telling of defeat and showing no returns of any sort for money spent in entry fees and carriage; but then

"Let Fate do her worst; there are relics of joy,  
Bright gleams of the past, which she cannot destroy."

This certainly is cheering, and the memory of bygone triumphs with now defeated birds makes a fine spot for some and an endless fund of grumbling for others. About the judging, we take the Judges' parts and always have done, for we know how easy it is to go round catalogue in hand and with the aid of

friends and exhibitors criticise the awards made by gentlemen who have been turned adrift into a show to judge in a certain time a certain number of birds without help of any sort or kind, often an attendant not being at hand even to hold a refractory specimen. Thinking thus, we wonder the awards here are ever made in these gigantic classes with the precision and accuracy they are, and this year we find about the usual state of things—some mistakes, and some wonderful awards, where previously unknown birds have been at once spotted in classes of many entries and containing birds of much note. Taking them on the whole, then, the awards are satisfactory, the arrangements are capital, the feeding good, the attendants courteous, the entries large, and the quality wonderful. So much then for prologue, now for criticisms.

**DORKINGS.**—Dorkings, as of old, head the list, and would a few years ago have been considered a show in themselves. We have certainly seen a greater number of excellent birds in the Coloured classes at some of the Birmingham shows, but the most captious critic could find but two or three faulty specimens in the prize list, and the Silver-Grey—and even more so the White classes—are of rare excellence. The season has evidently been a bad one for moulting, and consequently the classes for adults are in condition far behind those for young birds.

**Class 1.—Coloured cocks** head the list. We confess that we think the first-prize bird here overrated. He is a very large dark bird, but ungainly and shaky on his legs, and his comb is not in good order. Second is a smaller bird, but a thorough Dorking in shape, deep-breasted and black-tailed. Third is a grand bird, good in shape and feet, and in vigorous condition. We should certainly have been inclined to put him first.

**Class 2 for Coloured hens** contains twenty-one entries against nine cocks. The cup for the best adult bird went to this class. The winner is perfection in colour and in the pink of condition, though hardly up to the size of cup hens, and in this respect inferior to the second and third prize birds; still we think her well placed. Second is a very large bird, but not in such bright condition. Third very equal with the second, but a little scaly on the feet. Fourth a nice bird, and well placed. Mr. Bartrum's highly commended hen—a veteran winner, we think—is a fine bird. Many birds in this class are not well through the moult.

**Class 3, Cockerels.**—This we consider decidedly a good class, the winners being fairly ahead of the other competitors. First-and-cup is a darker bird than we like, with much bronzing on the wing coverts; but Coloured Dorkings must not be judged as birds of feather. He is good in shape and massive in limb. Second we thought, all round, the finest bird in the class, but probably his silvery colour prevented his being first. Third, Mr. Burnell's again, somewhat smaller than No. 2, but darker and very short on the leg. Fourth, a now-celebrated bird shown by Mr. Hans Hamilton, the cup-winner at the Alexandra Palace. We think he has seen his best days for this year, and looks jaded. It is no small honour to Mr. Burnell to have bred this bird as well as the second and third prize birds. Fifth, a bird in nice condition but in no way remarkable. Among the highly commended the best struck us as being Lord Turnour's Oxford winner, a good bird save in claws; a fine cockerel of Lady Dartmouth's, apparently thrown out by a swelled toe; a massive bird of Mr. Clarke's, and a Rose-comb (Badger), which if not overshadowed may make a fine cock.

**Class 4, Pullets,** did not strike us as being so good as the cockerels. Their colour has certainly been brought to great perfection, but we fear at the expense of form. First is a big bird, but not so good in colour as the second and third, and with remarkably white earlobes. Second is somewhat her inferior in size, but a beautifully coloured bird and in perfect condition. Third nearly a match to the second, rather less in bone. Fourth is not a large bird but good all round, we suppose her shape brought her into the prize list. Fifth-prize bird is small compared with her predecessors, with an old-fashioned dark red breast, which we like. Some of the highly commended birds are good. Mr. Parlett's (the Alexandra Palace winner), will make a grand hen. 107 (Bigg), is a good bird but inclined to dark feet. 70 (Lord Turnour), should, we think, have had a place in the prize list.

**Silver-Greys.**—Here we see a great advance on former years, very few cocks being shown with grizzly breasts, and hardly a hen with red in the wings. The cup for the best adult went to a cock. This award is, we unhesitatingly say, one of the most unfortunate we ever saw. The bird is indeed a large one, but his saddle and hackles are very yellow, his breast is splashed, his thighs are pure white, and his shrivelled comb hangs on one side. Second is barely through the moult, but a large and very faultless bird, and infinitely superior to the cup bird; as is also the third, not a large bird, but excellent in colour.

**Hens** are a nice class. First is a fine old hen of the darker shade of silver with good robin breast. We should have given her the cup. Second is a much lighter-coloured bird of good square shape. Third a very long and large hen; if we mistake not a winner in former years.

**Cockerels.**—First is a remarkable bird. We should have given him the cup. Second a nice cockerel. A less honest exhibitor than Miss Paaley would have pulled out some feathers on his legs. Third a small bird, but very silvery and well-coloured on breast. Commendations were sparingly given in this class, and many nice birds were unnoticed.

**Pullets.**—The cup went to a pale-coloured bird with a good robin breast. This is a rare combination, and we think meritorious. Second is a bird of the same type, as good in frame, but not so sound in breast colour. Third a fair pullet. The class as a whole we did not think so good as the cockerel class.

**Cuckoos** we consider a failure. The first cock had a bad comb and a nearly white tail, otherwise his markings are good. The second we thought a better bird. The third decidedly larger, but with badly-marked wings. The winning hens are all very dark; the first of medium size, the second and third very small.

**Whites** are good classes, numbering twenty cocks and fifteen hens. This shows the policy of dividing the classes, which we believe was conceded on Mr. Burnell's liberal gift of a cup conditionally. First is a fine cock, large and square, and in splendid condition. Second a pretty white cockerel, not large—the Oxford cup bird, we think. Third a very young and massive cockerel, promising to be a grand cock. We liked Mrs. Hayne's commended cockerel and an unnoticed one of Mr. Stratford's.

**Hens.**—Here Mr. Cresswell is again first with a lovely hen, which also carries off the cup. She is long-bodied, of pure colour, and faultless in comb and feet. Second is a pretty bird from the same yard in excellent condition. Third is a good short-legged hen. 212 (Mrs. Hayne) is a sprightly bird, but thrown out by crooked claws.

**Class 13 (Selling),** contains some valuable birds and bargains, but as usual in these classes the unions of cock and hen are somewhat ill-assorted birds. The first pen contains a grand dark cock with a poor, badly-coloured, little hen. Second and third are nice cockerels belonging to the same exhibitor, mated with very dark pullets hardly their equals. There are cocks in the class which would have probably won in the open classes.

**COCHINS.**—The Cochins are very good, but taking them as a lot we do not think them quite so good as last year. Perhaps the best class of Cochins is that for White hens, which is certainly wonderfully good; many of the other classes contain several fine birds, but no one class contains the number of splendid specimens as does that for White hens. Cochins prices seem as good as ever, and we hear of specimens realising extraordinary sums. Some go so far as to say Cochins have been the *pièce de résistance* of the season, and have come to the front in quality better than any other breed. We hardly think this, though acknowledging the merits of many of the Cochins birds, for we feel the Houdans have done wonders in 1875 in marching along the road that leads to complete and final success. But for the Cochins. **Buff** cocks come first on the list with half a score of entries. The winner is the champion cock of last year, and well, too, he looks on this occasion. He has come out a good colour, and looks as broad and massive as ever; still there is something about him which does not make him so startling to look upon as he was in 1874. Nevertheless, he should have had, we think, the cup for old Buffs before the Buff hen, even if he was not near the £21 piece of plate, which we know some think ought to have been his. The other birds in this class were good and well placed. We liked the third-prize bird very much; he looks as if he would make a grand stock bird. Mr. Darby's pen was empty. In old Buff hens we did not care for some of the awards; the third-prize hen was poor in every way, and we preferred many pens to her. The best hen in the class was, perhaps, Mr. Darby's unnoticed bird, but she had a cold in her eye, which we conclude threw her out; but even putting first and second as they were, one of the pens 253 (Lingwood), 254 (Hendrie), or 258 (Gwydyr), should have come in third before the hen with that honour. **Buff** cockerels were a nice lot. The winner was indeed a winner; he won first prize, his section cup, and the £31 cup for best pen in the Show; but whether he should have had the latter honour is a matter of great doubt. He is a nice showy bird, a little loose in one wing, but good in head and other points. Second a nice square bird of good sound colour. Third a large cockerel of fine shape and possessing many good points. Fourth another nice cockerel of fine colour with a pretty head. Mr. Lingwood's highly-commended pen was very good, and so was Mr. Taylor's. **Pullets** were a very choice lot, and the awards about correct. The first is very even in colour and good in shape, but a shade small; the second very beautiful in colour and grand in all points; and the third a smart pullet of great promise, and looks admirably in her pen. Fourth a large bird of nice shape, but not over-good in colour. 310 (Proctor) a very large but rather mottled pullet.

**Partridge** cocks were a fine lot. The winner was large and square; he has lost a serration of his comb, which makes him look rough about the head; he has a nice breast and thighs, and very golden hackles. For second place we should have gone to Lady Gwydyr's highly-commended bird; he is very rich in colour

and grand in shape, and when well through will scarcely be excelled; the second and third were, however, fine birds, and possessing much quality. Mr. Tudman's other pen (815) was a fine cock of good colour and square shape. The Partridge hens were very fine, and many of them wonderfully fluffed and pencilled. The winners were all good, and so were the highly-commended pens of Messrs. Jones and Percivall. Partridge cockerels were a fine collection. The winner large in body, strong in limb, and good in colour and head, and we thought well to the front. Second a very nice bird, well grown and well shown. Third another good cockerel of rich colour. We liked Mr. Shrimpton's pen 855 very much, for the cockerel, though now rather brown in fluff, promises to make a grand bird and to have a good head. Partridge pullets were excellent; we were delighted to see such splendid pencilling. The winner was small, but a gem for markings. The second was larger, and not much behind the winner in pencillings. Third a nice bird, also beautifully pencilled. All the noticed birds were good, and we thought this a very good class.

*Whites* made a grand display, no less than sixty-three entries being made. There were, however, many empty pens; among them in old cocks we noticed Messrs. Darby's, Whitworth's, and Woodgate's pens had no tenants. We liked the winner very much; he is very fine in colour, but then the whole class was remarkable for this. The second was slow on the legs and rather small, or else of superb colour. The third we liked immensely; he is grand in shape, legs, and head. Capt. Talbot sent five birds; of them pen 390 was evidently very ill, but his other four were all good and splendid in colour, but they all want more time to come out well, which they will doubtless do. White hens were superb, and we thought the winners well placed. The first was a picture in every way, and of exquisite colour. Second not so good in colour or comb, but large and well-shaped. Third very good, but closely pressed by one or two of the highly-commended pens. Every pen noticed was good, and we longed for prize cards to put on Messrs. Proctor, Whitworth, and Tindal's pens. White cockerels were not a very grand lot save the winners. Out of the dozen pens entered one third never came to the post, for the pens of Messrs. Shrimpton, Woodgate, and Talbot (3) were empty. We should say the second-prize bird closely pressed on the winner, for he is larger and better in head, though as yet not quite so massive. The third was good but badly shown, and Mr. Boissier's pen 428, though large, was much too coarse in every way, and looked dirty and out of condition. White pullets were good, and here quite a little scene took place. It appears that grave doubts arose in the minds of some of the Judges as to whether Mr. Acton Tindal's bird in pen 487 was a legitimate 1875 chicken or not, for it had its fluff and matured features so largely and strongly developed. Whether it is an 1875 pullet or no we will not pretend to say; but this we do feel, that the Judge jumped out of the frying-pan into the fire, for though Mrs. Tindal's bird was left out in the cold, the first prize was given to a bird which we venture to think is even older-looking in head, legs, and general appearances. The second pullet is very young, and should not have been in the list, we think, at all. We much preferred Mrs. Tindal's third-prize pullet, or that of Mr. Bloodworth, which was second at the Alexandra meeting, to say nothing of Capt. Talbot's very white and pretty bird.

*Black Cochins* were small classes, and only the cockerels really good. The old birds want more time, though Lady Gwydyr's pair were very good all round, and so were the second. In cockerels Mr. Darby walked his two birds in, one of them taking the cup; he is very grand in colour and shape, and beautifully feathered. Third also good but poor in comb. The pullets were an easy lot to judge, and no mistakes could well be made. The winner was rather hooked, but of good colour and shape. Second and third quite young and not yet developed; all the noticed birds were ditto—in fact, except for the cockerels, we do not think these Black Cochin classes so good as last year on the whole.

The awards in the Cochin sale classes we did not know; we waited till the bell rang to clear the Palace, but could gain no tidings, and had to leave without them. We were sorry for two reasons—for ourselves, because we knew we had the Cochin MS. to get in hand on Monday evening, and for the Society because it is often a check to sales when the cards cannot be upon the cheap pens on the first day. We noticed, however, that the cards were put up in a very slow way, and we never left the Palace on the first day so much in a fog as to the awards as we did in 1875, and we are sure in this many agree with us. Of the birds in this £5 class we much liked the Buff cockerel in Mr. Burnell's pen, and the White hen in Capt. Talbot's 499. Taking the Cochins, then, collectively, we think them a wonderfully fine lot, and showing signs of progressing even now.

*Brahmas*.—The show of this breed is an immense and magnificent one, upwards of five hundred pens being exhibited, pretty evenly divided between the two varieties. The office of a reporter is no easy one with such an enormous field before him to be reviewed in a few hours, and it is necessary to set

before us some definite and intelligible plan of criticism. It is impossible to describe accurately every winning bird when in some classes ten prizes are awarded; we shall attempt for the benefit of those who have not seen the Show firstly to point out the general principle on which the Judges seem to have made their decisions, and secondly to trace general improvements or deteriorations in the varieties. On the whole we think that we see a great general advance in the Light variety. The form of most of the winning birds is excellent, and such as was seen but here and there a few years ago. The Darks have reached apparently the *ne plus ultra* in beauty of marking, but we fear with some sacrifice of comeliness in the cocks and size in the hens.

*Dark* cocks numbered thirty-two. The cup-winner is an immense bird barely through the moult, very glossy, but we do not admire the angle made by his back and tail. Second is a hooked bird with good black breast and fluff. He also is deficient, as now are so many otherwise good Brahmas, in the beauty of a back gradually rising towards the tail. Third is not so large a bird, but beautifully striped on the neck-hackle, and with a better cushion than the first and second. Fourth we consider the best bird in the class; he has hardly got his full growth of neck-hackle yet, but he is perfection in marking, and has a bold densely-black breast. Fifth is not so good in size as the other winners, and rather rusty on the wing, still he is a bird sure of honours at any ordinary show. Hens.—The cup went to a bird very evenly pencilled all over, but we must confess that we do not like her shape. When we saw her her back certainly drooped towards the tail, but it may have been the fault of her attitude at the time. Second a thoroughly good hen inclined to have hooks, as are now most of the winners, but combining great clearness and beauty of pencilling with good size. Third a smaller bird, and slightly more inclined towards a brownish tinge, but with that lovely breast-pencilling which Mr. Peake now seems to produce so clearly. Fourth a bird with the markings on her breast of a singularly bright black; a want of shapeliness behind detracts from her beauty. Fifth, again, when looked at full face is a beautiful hen, but a grizzly tinge on her wings and in her fluff must have prevented her being placed higher. Mr. Lewis Wright shows a hen remarkable for size and great regularity of pencilling. Some good judges considered her the best hen in the class, but she is a little brownish. Mr. Dorchester's commended bird struck us as being of excellent Brahma shape.

Cockerels this year have two classes, the second being for birds with mottled breasts. The natural inference is, that the first class is for Black-breasted birds, but strangely enough one prize went to a bird with much white markings on his breast. The cup bird is one of Mr. Lingwood's best type. He is perfection in leg-feathering, and has a small highly-bred head. He reminded us of the beautiful cup bird of two years ago. Second is not so large a bird, but quite as good in shape, with very dense pencilling on the neck-hackle. Third is the bird which we think should have been in the next class. He has the fault which we have observed in other birds of 'Miss Douglas Pennant's, otherwise very good—viz., a want of fulness in breast. Fourth a small bird, but of very pretty form. His tail is, perhaps, a little too Cochin-like. Fifth long-tailed and rather ungainly, but apparently timid, which prevents a bird doing himself justice. Sixth a bird which we should have put higher. He is tall and perhaps a little long in shanks, but remarkable for intensely dark under-feathering. The four other prize birds are, generally speaking, in our judgment decidedly inferior to the six foregoing ones. Seventh is spoilt by an ugly comb; eighth is a well-shaped bird but rather yellow, with white in tail and brown in wing; ninth a fair bird with poor comb; tenth somewhat narrow, or would have been higher. Mottled-breasted cockerels are, generally speaking, indifferent. This we think a satisfactory sign, showing that there is some real connection between a black breast, which has of late been thought almost a *sine quâ non*, and general good points. The first and second birds are well ahead. We could not but remark the difference between the poor leg-feathering of Mr. Lingwood's bird here and that of his magnificently-feathered cockerels in the preceding class. No. 2 runs No. 1 hard. The other three prize birds really do not deserve comment. Pullets.—This class is a very large one (ninety-seven entries). As we remarked last year, size and form in pullet-breeding seem now too much sacrificed to marking, still there are many birds in this class of grand shape, and we were glad to see them come in for their share of prizes. The cup bird reminds us much of the cup bird of last year; she is exquisitely pencilled, a little light towards the top of the breast, but rather sparsely feathered on the legs. Second a bird which we did not much admire either as to head or markings. Her ground colouring is a little brown, and the black pencillings not very defined. She has excellent foot-feathering, and is slightly hooked. Third is finely shaped, perhaps a little mixy on the wing, with distinct breast-pencilling of the rounder form. Fourth is a fine large pullet, well placed, evidently on account of her size, for her markings are a little indistinct.

Fifth a prettily pencilled bird, not unlike the first. Sixth correctly and evenly marked, but with greater breadth of black than we like in the pencilling. Seventh fair both in form and size, moderate in colour. Eighth a fine pullet. Ninth small and well pencilled. Tenth a remarkable bird, which in our judgment should have been far higher. We say this with less diffidence, because we made our note before looking at the owner's name, which would, of course, lead one to expect merit. Her pencilling, especially on back and wings, is very fine, and she is shapely too.

The Five-guinea Selling class contains, as a rule, birds far above that value, which doubtless are sent on the chance of their winning prizes or being run up at the auction. The better birds which fail so to do, and are consequently sold in the ordinary way, cause no little rivalry and excitement at the sale office. The hen in the first-prize pen struck us as remarkable for utter absence of brown in her colouring, the ground being white and the pencillings black.

*Light Brahmas*, as we have already said, are making great strides in form. Each year we see fewer of the narrow long-shanked birds which once were common. The cup cock struck us as being the most perfectly shaped *Brahma* of either variety in the Show; he is good, too, in colour, and all that could be desired in leg-feathering, his feet amply clad, and masses of quite soft feathers curling round his hocks; if only a little size could have been added he must have been very nearly the winner of the champion cup. Second a tall bird, not equal in shape to No. 1, with very dark under-feathering. Third too high in comb, but a broad bird, and he has the merit of a very good hackle falling on a beautifully white ground. Fourth a big bird not in first-rate condition, and a little yellow; his hackle is good, and his leg-feathering magnificent. Fifth is a small bird of nice form and hackle, rather like the cup bird on a reduced scale. The class is decidedly a good one. *Hens*.—The cup was given to a gigantic and grand bird, apparently not quite dry from the wash-tub; her form is such as we rarely see, her colour clear, and hackle distinct. Second a far smaller bird, very white, and with good neck-marking, but poorly feathered on the legs. Third a bird good in shape and feathering, not so clear in ground colour as the first and second, fair in size. Fourth the same type of bird as the second. Fifth a small bird, and almost white in tail, but most excellent in ground-colouring, and well hackled.

*Cockerels*.—Mr. Horsfall is to be congratulated on winning the cup for cockerels as well as for cocks. His bird in this class is not equal to his adult bird; he is well-shaped, very fairly feathered, and nicely marked, his failing being a somewhat ugly comb. The second prize must have been given for form; the winner has little neck-hackle, and is small and under-feathered, still his shape is good, and we could not see much reason for the great fault which we heard made with the award. The third award we do not like; the bird's comb flaps, and his tail is too prominent a feature; all seems to tend towards it, and so he is tilted forwards. Fourth is a nicely feathered bird, but devoid of hackle. There is a gap between him and the fifth, which is a narrow bird and flecked on the back. Sixth is a most remarkable bird, we should have placed him first or second; his special beauty is his faultlessly white colour; his size and leg-feathering are also all that can be desired. Seventh we thought a poor bird and rather yellow. Eighth is somewhat devoid of hackle. Ninth we liked better than many of the earlier winners; he is large and very fairly marked. Tenth is small, perfect symmetry being his strong point. *Pullets*.—The early winners in this class again we thought excellent in form. The cup bird, in addition to being well shaped, is beautifully white, but too light in tail to please us; a rich black is here, to our idea, a great ornament. Second is not so clear on the back, but makes up for this defect in shape. Third is a little tinged and slightly hooked, otherwise a very nice pullet, and good in build. Fourth has a correct amount of leg-feathering and nice hackle. These four birds are all broad; the fifth is not so, and is more of the old *Light Brahma* form, still she is a pullet sure to win. Sixth an excellent bird; we should have put her higher; her neck hackle is splendid and her back clear, her under-feathering dark, yet not peeping through in flecks. Seventh deficient in hackle, or would have been higher. Eighth a well-grown fairly-marked bird; we prefer her to her owner's fifth-prize winner. Ninth pretty, but too small and light in hackle. Tenth not remarkable.

*Five-guinea Selling class*.—As a rule the birds in this class seemed deficient in the distinctive dark markings of the variety, though in many cases good in size and form. The first-prize pair were well placed. The second contains a well-formed cock. The class has the large number of thirty-five entries.—W. AND OTHERS.

#### THE FRENCH CLASSES.

As I anticipated, the promise held out by the Alexandria Show was fully borne out by the grand Exhibition at the "old shop;" and a finer collection of birds than those brought forward in the classes in which I am especially interested (*Houdans* and *Crève-Cœur*) was never exhibited. I wish that I could add that the judging was equally as good as the birds; but I am able

to give an unprejudiced opinion, for I was neither an exhibitor nor a special friend of any exhibitor, although I know many of them; and although it is, we are told, a difficult matter to be impartial, I believe my observations will be endorsed by many exhibitors. These are points in which, of course, differences of opinion may be allowed to judges. One likes the leaf comb, and another the antlered one; one prefers dark-coloured birds, and another light, and exhibitors will not complain, I believe, if a judge gives his preference to either one or other of these types of birds; but the veriest tyro in *Houdans* knows that red hackles are a disqualification, that an outside spur is a blemish, yet in the cockerel class a bird with one of these defects and with a wry tail takes first prize, while one full of red hackles in his neck and tail takes a third. With regard to the latter I can safely say that, as an old *Houdan*-breeder, had he been in my yard I should long ago have had him to table. Again, what are we to say when hens and cocks are exhibited as cockerels and pullets and gain a prize? I am not sure that this is always done with a guilty knowledge of the fact. I know one case in to-day's showing where a bird was exhibited at a provincial show as a pullet, obtained a cup, is claimed, and then exhibited as a pullet here. Of course the buyer can with justice say, "I bought it as such, and therefore I can exhibit it;" but the Judges ought to be able to distinguish in some of the cases at any rate. Where judging is so faulty as in some of the classes to-day there is no merit in winning a prize; and, as one gentleman said, if all the numbers were put into a hat and drawn there would be more satisfaction. Let it be borne in mind that it is not partiality or unfairness that is complained of, but incompetency. And now a few words on the exhibits.

In the *Houdan* cock class 1073, first prize, is a grand bird of Mr. Woods, in every respect good, although not having what some insist upon in *Houdans*, the leaf comb; still he is a magnificent fellow, and well deserves his position. 1074 is a fine bird, so is 1076 with the genuine leaf comb. 1075 has a thorough *Crève* comb, but good. 1082 light in colour, but fine. 1087 (Mr. Copplestone) second, a fine bird, but rather queer about the feet. 1088 a very large bird. 1090—why was this bird brought? and yet two years ago the owner exhibited a fine bird here which took first. 1089, too small a comb, and with a ragged crest. 1092 a very fine bird, good in colour. 1093 also a very good bird. The hens were very good. 1094 very fine old bird; has seen some seven or eight summers. 1096 good, but queer in the feet, and with an outside spur. 1098 very good, capital in colour. 1114 very fine bird, good in size and colour. 1116 good, but somewhat small. In cockerels there were some strange vicissitudes of fortune: birds that had won cups elsewhere not noticed—thus 1128, inclined to squirrel tail, won the cup at Oxford, not noticed here; 1129 which won the cup at the Alexandria also unnoticed; 1188, first prize, had, to my mind, many points against him—a wry tail, bad fifth claw, and a queerish comb; he had a magnificent crest, and was very large and good. 1153 was a flagrant case of bad judging. Pullets were good; but if the first prize, 1162, was a pullet, I have very antiquated notions of what a pullet is. 1174 very handsome, but somewhat small. 1188, third prize, pretty marked bird, but rather small.

The judging in *Crèves* was not so bad, and indeed in some of the classes no exception could be made. 1192 was a magnificent bird in splendid condition, and, if I mistake not, this is the third year running that Mr. Hibbert has carried off the first prize here with him. 1202, the second-prize bird, is a fine fellow, and if in as good condition as the previous one would have run him very hard for first. 1206, a good bird, fine shape, and good in colour. Hens were a fine class, although I think some of the awards might have been well altered. Thus, I think 1218, which took second prize, was a better bird than 1219 which had first. The crest of this latter came so much over the face as to make it especially ugly. 1211 was also a good bird, and ought, I think, to have been better placed. There were some grand birds exhibited in the cockerel class. 1243, first-prize, was well worthy of the place he took, grand in size and colour. 1249, third, was also a grand bird; I should have preferred him to second. 1241, highly commended, was a good bird also, but small. In pullets the first prize was given to a very splendid bird, 1258, of Mr. J. J. Malden's. Indeed a finer one has rarely if ever been shown; it was hatched very early in the year and has been well taken care of. 1252, second, nice bird, but large and fine. 1267 was good but rather small. 1266, a nice bird, but in bad condition.

There were other noticeable features to which I may return, but time and space limit me now.—D., Deal.

#### BANTAMS.

*GAME BANTAM* cocks are better than the hens, but a tendency to over-size exists in both. First *Black Red* hen excellent; second cock capital. Among *Brown Reds* the first cock was far ahead of the rest; the hens better than their mates. *Duck-wings* no advance. *Piles*, first-and-cup a very choice cock, and the hen, same owner, his equal. *Wheatens*.—This colour not fixed yet, some of the various shades one-half *Duckwing*. The *Blacks* well up to the mark; all prizes deserved. The *White*-

booted fair. Second-prize birds (Mr. Woodgate's) well shown. The *Sebrights*.—First and second very good; third large. There was rather a falling-off in these pretty pets.

We have spent so much time, and given so much space to the Dorkings, Cochins, Brahmas, French, Bantams and Pigeons, that we must defer the remarks on the remaining breeds till next week, when we promise them the same justice as we feel the criticised classes of this week enjoy.

#### PIGEONS.

##### HOW I EXPECTED TO SEE.

TOM HOOD the elder and wittier wrote something like this—

"No night, no day,  
No 't'other side of the way,  
No sun, no moon, no stars."

and a great many other no's, ending with No-venber; but he said nothing about no dry land. Had he lived to this November he would, though—that he would. Water everywhere: no trains from Oxford to Didcot—stopped by water; engines running through water, "hissing hot, air, hissing hot," like Falstaff when thrown from the "Merry Wives" buck-basket into the Thames at Datchet Mead. Dark, too, so dark—rain, darkness, misery. I'll go, however, through water, almost through fire, to the Crystal Palace Show. See it? that's another thing quite. I may see it, peep at the birds with gas jets in front of the pens, perhaps with itinerant link boys. Happy thought that, make a present of it to the Committee. Call on my way and get a magnifying glass—another happy thought. I will try and see the Show, for what the best run of the season is to the hunting man such is the great Crystal Palace Show to the poultry and Pigeon fancier—a thing to talk of, enjoy, and reflect on. But I do not expect to see it to advantage.

##### HOW I DID SEE.

Floods abated, rain gone, sun out, the old palace of glass shining diamond-like. Birds, my birds—that is, the Pigeons, cooing as if at home, joyful in the day's joyfulness; all is bright and pleasant. I see the Show to perfection.

I regret to have to grumble, but the good Judges are a little behind with the "cards." The rows of chairs—uncomfortable barriers—prevented one getting to the Pigeons. Noon, then one o'clock comes, then two, still the barriers. But never mind, Pigeon friends, some "fray the far north," sit with me on the chairs, and though we chafe a little, we talk and enjoy ourselves. At length, at long last, we are in; chairs moved, we scamper in. The "cards" are now only up in some classes, not all.

Now for the birds. The numbers are so great, the pressure for space is also so great, that I must speak of the birds generally rather than particularly—instead of writing a pamphlet on the Show, notice only the chief features and the special attractions.

The *Pouters*.—These just kept up their old place, but certainly there was no advance. The Blue-pieds showed the uncertainty of Pigeon-fare, for Capt. Hill's grand old bird, No. 2584, had only a "commended," and a splendid cock, 2685, was not noticed. A bird of fine colour (Fulton) won. Among the Blacks no doubt the first prize was ahead of his class. Second had a nasty blue tinge; third good. Reds and Yellows poorish in colour; though in Whites the first was long and large, yet a very fine bird. No. 2610 (Watkins), was, rather curiously, unnoticed. He has a crop indeed, and is a very fine Pouter. As to the other Pouters Mr. Fulton's first-and-cup Blue hen was a fine well-judged bird, and second (Gresham) very good. The White hen (2670) first—now Fulton's, late Heath's—was admirable. A Chequer hen I could not admire won, a beautiful graceful Dun being second. Among the *Pouter* Whites won all; the second were two cocks which should not have been. The class good—all noticed.

*Carriers*.—These birds are very fine and the classes heavy. Certainly these have gone on, Blues particularly. None were mere bits of things. The young birds promise well, and had four prizes in cock and hen Blacks.

The *Dragoons* are now wonderfully popular. Blues excellent. Reds showed a bird, first-prize cock, of wonderful colour, rich and sound. No one could pass him, and few but looked again. At a distance the bird shone up conspicuously from his brilliant plumage. The Yellows were lovely, and the perpendicular light falling on them showed off their soft sweet colour. The Whites formed a fine class. Grizzles are well enough now and then.

*Almond Tumblers*.—Here was the advance, and all praise to Mr. Bequiant for causing it. The colour is now fine, and artificial head and beak go for less. It is now the whole bird instead of one part of him. Mr. Ford's bird, first prize, is a gem, and Mr. Merok's first hen the same; both grand in ground colour and feather. Well-broken Almonds are Almonds now and no mistake. The second-prize young hen (Hallam) is a choice little bird of exquisite shape, in that and also better than the first. The excellency of the Almonds is the feature of this Show.

The Short-faced *Balds* show what one persevering man may do. That man is, of course, Mr. Woodhouse of Lynn. His first Blue is very superior, and Mrs. W.'s second Red worth a long

walk to look at. The Any other variety of Short-faces brought together some fine feathered birds, chiefly Red and Yellow *Agates*.

*Barbs*.—The old birds are short in numbers; the young birds promising, and deserved their four prizes.

*Jacobins*.—Here was another advance. The first Red (J. Thomson) had a perfect rose. The Yellow first-and-cup (Fulton) is indeed good—colour, hood, chain, carriage. The Blacks and Whites, the latter getting more numerous, are very attractive. First-and-cup a Black, grand colour; second a neat White. The present fault seems to me to be the hoods not coming forward enough. *Fantails* very fine, fourteen noticed in Whites. *Nuns* and *Trumpeters*, the last are the best.

I think all, save the very prejudiced, must have owned that English *Owls* ought to be preserved. They are noble birds, and their beauties distinct from the pretty foreigners. I was pleased to see such a large class. First and second grand. The Foreign *Owls* few, but choice; the winners all White.

The *Turbits* again good. Mr. Daw first and second in Blue *Silvers*, and he did not have more than his *due*. The cup Red (Fulton) such a solid colour, a *rara avis*, and good Yellows followed. I want to see more Blacks.

The *Maggies*.—First good Black, third a very good Red. The *Rants* in few hands, but up to the mark. The *Flying Tumbler* class showed some neat birds, and not too short-faced. The Any variety hardly equal to former years. *Mealy Frillbacks* most noticeable.

The four-pair-bird prizes must have a word. The cup went to Mr. Fulton. He showed such *Jacobins* for hood and chain, but, tell it not in Dundee, they were low-cut and clean-thighed. The row of large cages is a grand feature, and I wish I could give more printing space in praise of their contents, but it cannot be had. The Pigeon show was, save two pens, as large as last year. The poultry fell off in numbers, but not the Pigeons. —WILTSHIRE EXHIBITOR.

Mr. M. Martin was awarded an extra second prize for his excellent collection of birds in the class for four pairs collections of Pigeons, Class 193, No. 3724.

Mr. Vander Meersch was unfortunate in not having some excellent birds penned in time for judging.

Food of every kind is supplied by Mr. Pratt of Lupus Street. The Pigeon department is under the sole management of Mr. F. Crook. The awards are as follows:—

*Agates*.—L. G. W. Stratford, A. Darby, Rev. F. Tearle, T. C. Burnell, Mrs. M. A. Hayde.  
*Dorkings* (Any variety).—1, Mrs. A. Tindal. 2 and 3, F. Cawa. 4, H. W. Beachey. 5, Viscount Turnour, W. Roe, jun., W. H. Denison, T. Moore, L. G. W. Stratford, T. C. Burnell, W. Harvey. 6, W. E. Middlecott, T. Charrington.  
*Cochins* (Cinnamon or Buff).—Cock.—1, W. A. Burnell. 2, J. Walker. 3, Henry Lingwood. 4, E. P. Percival, J. Bloodworth, W. A. Taylor.  
*Cochins* (Cinnamon or Buff).—Hen.—1 and 2, C. E. Proctor. 3, R. P. Percival. 4, W. White. 5, Mrs. J. Hendrie, Lady Gwydyr, W. A. Taylor. 6, Henry Lingwood, W. A. Taylor.  
*Cochins* (Cinnamon or Buff).—Cock.—1, Cyp, and 4, Mrs. A. Tindal. 2, Henry Lingwood. 3, W. A. Taylor. 4, T. J. Harrison, Henry Lingwood, P. Ogilvie, W. A. Taylor, H. Tomlinson, W. A. Burnell, J. Everett. 5, W. E. Smith.  
*Cochins* (Cinnamon or Buff).—Pullet.—1, Mrs. A. Tindal. 2, W. A. Burnell. 3, A. Darby. 4, G. H. Proctor. 5, Mrs. A. Tindal, Mrs. Alsop, G. H. Proctor, Henry Lingwood. 6, J. Benton, W. A. Burnell.  
*Cochins* (Partridge).—Cock.—1, W. A. Taylor. 2, E. Tudman. 3, Mrs. Tindal. 4, T. Stretch, E. Tudman, Lady Gwydyr, W. H. Crabtree, J. G. Pearson, W. A. Taylor.  
*Cochins* (Partridge).—Hen.—1, Mrs. A. Tindal. 2 and 3, R. P. Percival. 4, T. Stretch, J. H. Jones, W. A. Taylor, E. Tudman.  
*Cochins* (Partridge).—Cock.—1 and 2, Mrs. A. Tindal. 3, J. H. Jones. 4, F. Bennett. 5, Mrs. W. Steven, Mrs. J. Hendrie. 6, T. Stretch, E. Tudman, D. Lewis.  
*Cochins* (Partridge).—Pullet.—1, H. Tomlinson. 2, Mrs. A. Tindal. 3, J. H. Jones. 4, T. J. Harrison, 5, J. H. Jones, R. P. Percival, E. Tudman, Mrs. A. Tindal, Lady Gwydyr. 6, G. Lamb, J. K. Fowler.  
*Cochins* (White).—Cock.—1, E. Tomlinson. 2, T. H. Waterman. 3, R. P. Percival. 4, Capt. G. F. Talbot. 5, J. Bloodworth, J. H. Nicolls.  
*Cochins* (White).—Hen.—1 and 2, Mrs. A. Tindal. 3, W. A. Burnell. 4, Capt. G. F. Talbot. 5, Mrs. A. Tindal. 6, Mrs. J. T. Holmes, Capt. G. F.

Talbot, W. Whitworth, jun., R. S. S. Woodgate, G. H. Proctor, R. A. Boissier, c. J. Turner, R. A. Boissier.

**COCKS (White).—Cockerel.**—1, H. Tomlinson, 2, M. Leno, 3, A. F. Faulkner, c. R. A. Boissier.

**COCKS (White).—Pullet.**—1, J. K. Fowler, 2, W. A. Burnell, 3, Mrs. A. Tindal, 4, J. Bloodworth.

**COCKS (Black).—Lady Gwydyr.**—1, A. Darby, 2, G. Fortey.

**COCKS (Black).—Cockerel.**—1, Cup, and 2, A. Darby, 3, W. Badger, 4, T. Asplen.

**COCKS (Black).—Pullet.**—1, J. Turner, 2, T. Asplen, 3, A. Darby, 4, Lady Gwydyr, 5, E. Kendrick, jun., Miss E. Mansel, G. D. Harrison.

**COCKS (Any variety).**—1, Mrs. J. T. Holmes, 2, Mrs. A. Tindal, 3, C. Sidgwick, 4, W. A. Burnell, 5, Capt. G. F. Talbot, 6, G. Shrimpton, W. A. Burnell, P. Ogilvie, W. A. Taylor, H. Tomlinson, E. P. Percival, T. M. Derry, C. Carr, Mrs. A. Tindal, Capt. G. F. Talbot, T. J. Saltmarsh, C. Bloodworth, 6, M. E. Smith, G. Ellis.

**BRAHMAS (Dark).—Cock.**—1 and Cup, Rev. G. Watson, 2, E. Kendrick, jun., 3, G. F. Ansell, 4, Horace Lingwood, 5, Hon. Mrs. B. Hamilton, 6, R. P. Percival, Horace Lingwood, W. Dorchester, L. Wright, T. F. Ansell, c. Miss E. O. Shuter, Dr. J. Holmes.

**BRAHMAS (Dark).—Hen.**—1, Cup, and 4, T. F. Ansell, 2 and 3, Rev. J. D. Peake, 5, F. Holbrook, 6, Horace Lingwood, 7, G. Maples, jun., L. C. C. R. Norris, F. Bennett, Miss D. Pennant, L. Wright, J. Way, c. E. Pritchard, J. H. Pickles, W. Dorchester.

**BRAHMAS (Dark).—Cockerel.**—1, Cup, 2, and 3, Horace Lingwood, 2, Hon. Miss D. Pennant, 4, F. Bennett, 5, J. Rimmer, 7, W. R. Garner, 8, H. Feast, 9, E. P. Percival, 10, T. Pomfret, 11, E. Pritchard, Hon. Mrs. B. Hamilton, E. Ryder, W. A. Peel, Dr. G. A. Angier, c. Moulson, c. L. Wright, B. B. Glover, Rev. J. Richardson.

**BRAHMAS (Dark).—Cockerel.**—1, Horace Lingwood, 2, Hon. Mrs. B. Hamilton, 3, Hon. Miss D. Pennant, 4, S. Lloyd, 5, J. Brookwell, 6, L. C. C. R. Norris, c. T. Pomfret, Horace Lingwood, J. Harvey, M. Leno.

**BRAHMAS (Dark).—Pullet.**—1, Cup, and 5, E. P. Percival, 2, W. R. Garner, 3 and 4, Horace Lingwood, 4, Hon. Mrs. B. Hamilton, 5, E. P. Percival, 6, Newnham & Manby, 7, Dr. J. Holmes, 8, J. Swan, 9, E. Kendrick, jun., 10, E. Pritchard, Newnham & Manby, W. Birch, R. B. Wood, F. Bennett, E. Ryder, L. Wright, 11, J. Evans, F. Bennett, Rev. T. C. Peake, L. Wright, E. Durand, E. Bennett, Miss D. Pennant, T. F. Ansell, Rev. G. W. Joyce, Rev. J. D. Peake, Horace Lingwood, W. Dorchester, T. Wakefield, Dr. J. Holmes, E. Kendrick, jun., Rev. A. Van Stranzenesse, G. D. Harrison, E. P. Percival, S. Alloway, jun., R. B. Wood, J. Hill, Hon. Mrs. B. Hamilton, N. Edgill, P. Ogilvie, T. P. Ye, c. Miss E. C. Schuter, F. Bennett, Newnham & Manby, L. C. C. R. Norris, F. Le Sueur, Mrs. Griggs, E. Durand.

**BRAHMAS (Dark).—Pullet.**—1, Mrs. A. Tindal, 2, H. Beldon, 3, W. M. Crabtree, 4, T. F. Ansell, 5, W. H. Ward, 6, R. P. Percival, 7, Miss E. C. Schuter, G. Maples, jun., 8, J. Swan, c. Mrs. J. G. Hepburn, Hon. Mrs. B. Hamilton, J. Lyon, Rev. J. D. Peake.

**BRAHMAS (Light).—Cock.**—1 and Cup, R. E. Horsfall, 2, R. P. Percival, 3, P. Haines, 4, J. Bloodworth, 5, Mrs. W. C. Drummond, 6, R. Bird, Dr. G. A. Angier, R. E. Horsfall, E. Lingwood, P. Haines, c. D. Hare.

**BRAHMAS (Light).—Hen.**—1 and Cup, Mrs. A. Tindal, 2, S. Sambrook, 3, P. Haines, 4, J. Turner, 5, Rev. G. Watson, 6, S. Lucas, Mrs. Peet, Rev. G. Watson, S. H. Lloyd, Mrs. E. Heyn, Horace Lingwood, Mrs. J. T. Holmes, W. M. Crabtree, T. Dean, P. Crook, c. J. Long.

**BRAHMAS (Light).—Cockerel.**—1 and Cup, R. E. Horsfall, 2 and 10, T. A. Dean, 3, S. Wadley, 4, Capt. W. Savile, 5, S. Lucas, 6, Horace Lingwood, 7, J. Turner, 8, H. Stephens, 9, J. T. Hinks, 10, R. Bird, Mrs. Peet.

**BRAHMAS (Light).—Pullet.**—1 and Cup, Capt. W. Savile, 2, Dr. G. A. Angier, 3, G. W. Petter, 4, J. Birch, jun., 5 and 6, Horace Lingwood, 6, C. H. Wakefield, 7, R. E. Horsfall, 8, Mrs. A. Tindal, 10, Mrs. G. Bain, 11, Capt. W. Savile, 12, R. Bird, Dr. G. A. Angier, G. W. Petter, R. E. Horsfall, Mrs. J. Walsh, R. J. Foster, J. Benton, P. Haines, J. O. Harrison, G. B. Ladd, c. R. J. Lessall, G. W. Petter, C. Martin, J. J. Hewitt, Mrs. Peet, J. Widdowson, E. J. Foster, T. A. Dean.

**BRAHMAS (Light).—Pullet.**—1, G. W. Petter, 2, and 5, Capt. W. Savile, 3, R. P. Percival, 4, Mrs. A. Tindal, 5, Mrs. F. Cheshire, 6, S. Lucas, 7, E. Cleaver, P. Haines, Rev. G. Watson, M. Hedley, E. Mannoch, T. A. Dean.

**SPANISH.—Cock.**—1 and Cup, D. M. Mills, 2, Mrs. Allsopp, 3, F. Waller, 4, T. Moore.

**SPANISH.—Hen.**—1, E. Jackson, 2, J. Thresh, 3, J. Walker.

**SPANISH.—Cockerel.**—1 and Cup, A. Hewes, 2, and 3, G. K. Chilcott, 4, J. Walker, P. F. Le Sueur.

**SPANISH.—Pullet.**—1, Mrs. Allsopp, 2, H. Goddard, 3, W. Notlage, 4, E. Jackson, J. T. Parker, J. Boulton, H. Goddard, G. K. Chilcott.

**HOUDANS.—Cock.**—1 and Extra, R. B. Wood, 2, W. H. Copplestone, 3, J. Swan, 4, E. B. W. Peel, W. Dring, 5, G. Morris, W. O. Quibell, W. Whitworth, jun., 6, G. D. Harrison, W. Outack, jun., Mrs. Vallance, W. Dring, G. W. Hibbert.

**HOUDANS.—Hen.**—1 and 2, Mrs. Vallance, 3, C. Morris, 4, G. D. Harrison, 5, W. Dring, D. Lane, W. O. Quibell, 6, S. W. Thomas, c. P. Hanson, Mrs. N. Grenville.

**HOUDANS.—Cockerel.**—1, W. O. Quibell, 2 and 3, R. B. Wood, 3, J. K. Fowler, 4, G. D. Harrison, 5, W. Dring, 6, W. O. Quibell, 7, W. Dring, 8, E. A. Bostell, W. Dring, 9, W. O. Quibell, 10, W. Dring, 11, W. Dring, 12, W. Dring, 13, W. Dring, 14, W. Dring, 15, W. Dring, 16, W. Dring, 17, W. Dring, 18, W. Dring, 19, W. Dring, 20, W. Dring, 21, W. Dring, 22, W. Dring, 23, W. Dring, 24, W. Dring, 25, W. Dring, 26, W. Dring, 27, W. Dring, 28, W. Dring, 29, W. Dring, 30, W. Dring, 31, W. Dring, 32, W. Dring, 33, W. Dring, 34, W. Dring, 35, W. Dring, 36, W. Dring, 37, W. Dring, 38, W. Dring, 39, W. Dring, 40, W. Dring, 41, W. Dring, 42, W. Dring, 43, W. Dring, 44, W. Dring, 45, W. Dring, 46, W. Dring, 47, W. Dring, 48, W. Dring, 49, W. Dring, 50, W. Dring, 51, W. Dring, 52, W. Dring, 53, W. Dring, 54, W. Dring, 55, W. Dring, 56, W. Dring, 57, W. Dring, 58, W. Dring, 59, W. Dring, 60, W. Dring, 61, W. Dring, 62, W. Dring, 63, W. Dring, 64, W. Dring, 65, W. Dring, 66, W. Dring, 67, W. Dring, 68, W. Dring, 69, W. Dring, 70, W. Dring, 71, W. Dring, 72, W. Dring, 73, W. Dring, 74, W. Dring, 75, W. Dring, 76, W. Dring, 77, W. Dring, 78, W. Dring, 79, W. Dring, 80, W. that has been written about the clashing of shows I find there are four other exhibitions on the same date, and Canterbury the day after. I have heard from the Hon. Secretary of the Ipswich Show that he will forward any specimens exhibited there to any other show if exhibitors will send him the labels."

### CAGE BIRDS AT THE DERBY SHOW.

THE general arrangements were conducted tolerably well, still there are one or two matters that in the future it would be well for the Committee to alter—viz., the setting forth a day for judging, and not letting it be done on the first day unless before the time of opening the Show to the public. Some of the prize cards were not placed upon the cages until daylight had about gone; and as to the detached list of prizes, when it did appear in the form of a tabular key to the already-issued catalogue, I may remark that more credit (if any) was due to the compiler for the intricacy of it than for the utility to exhibitors, visitors, or members of the press.—QUIZ.

**HANLEY SHOW.**—The winners of the three special prizes for Pigeons were awarded, in their sections, one to Mr. Fulton's Carriers, one to his pair of Barbés, and the third to the Rev. Mr. Serjeantson for his White Fantails. As at the two former shows Mr. T. H. Ridpath judged the Pigeons on this occasion.

### THE BRITISH BEE-KEEPERS' ASSOCIATION.

I AM much pleased that the Hon. Sec., Mr. E. Laurance Cleaver, has noticed my remarks touching the shows. He refers me to the catalogue offering £10 in prizes for "the best and largest harvest hive of honey in the comb." The schedule of prizes which he refers to was sent to me, but if I remember aright the £10 was offered by two gentlemen through the Association, but not by it. Indeed one of the gentlemen—viz., the Hon. and Rev. Mr. Bligh—wrote a letter suggesting to the Committee the importance of offering such prizes. The effort made by the hon. and rev. gentleman was most commendable. Last year I suggested that handsome prizes be offered for the heaviest swarms, also for the greatest results in weight (not in comb merely) from one stock hive managed on any system. My suggestion is distinctly different from Mr. Bligh's if I understand him rightly; and I believe mine is of far greater importance, and if adopted will help to advance apiculture much.

How is it that the Association does not offer prizes for such results? and how can the Secretary of that Association or any one else expect to see 2 or 3 cwt. of hives exhibited when no prizes are offered for them? Will the Secretary undertake to do his best next year to offer prizes for such? and if the Committee will not yield to his entreaties in this direction, will he promise to pay the carriage merely of such exhibits? I care not for the honour of taking prizes; I have never competed for one in my life, and never wish to compete; but if next year be a favourable one for honey, I will send up to the Crystal Palace Show the results of one or two stock hives, if the Association will pay their carriage. What more can I do? What else can be done if prizes and encouragements are not offered by the Association?—A. PETTIGREW.

### HIVE COVER.

I HAVE made a hive cover which might be useful to some of your readers, and which I think good and cheap. I procure 2 yards of the material of which rick covers are made (more or less according to size of hives), which I cut so. 1 and 5 are

Fig. 97.

sewn together to make a piece like the others, 3 is turned up and down; the four pieces are then joined with the narrowest ends uppermost. It must be well sewn with thread on purpose, to be bought with the material. It must be well done. I had a charwoman, a shoemaker's wife, who thoroughly understood it. I then had it well painted.—TRICERS.

**SPURIOUS HONEY.**—A correspondent writes from the north of England: Owing to the bad honey season all sorts of inventions to manufacture honey are being attempted, and it may be well to put purchasers on their guard. Recently one of our grocers was supplied for sale with two small supers, which looked very nice. On asking the grower if he had any more he replied that he had one other large super, which he promised to bring the following day. He did so, and its size aroused the suspicions of the grocer, who fortunately happened to be a bee-keeper. On testing the so-called super honey it was found to consist of nothing but raw (or preserving) sugar. The grower was taken to task, and obliged to confess that as the season had been so bad he had constantly fed his bees with raw sugar at 8d. per lb.,

for which he was expecting a return of 2s. per lb. for the honey (?)—BETA.

THE length of the report of the Crystal Palace Show compels us to omit other reports and communications until next week.

### OUR LETTER BOX.

**FOWLS IN SMALL SPACE (R. D.).**—You cannot keep more than a cock and three hens in a space 12 feet by 9 feet. You do not say whether the quarter of the grass run is part of the 12 feet. If it is not, you may keep more hens. If you mean a quarter of an acre the three might be eight hens.

**REARING DORCHINGS (J. D.).**—The description you give leaves nothing to desire for Dorchings, as it possesses all that is necessary. They are essentially the fowl of the homestead, and will be found far more profitable than mongrels, or even half-breds. There used to be a good sale in York for good poultry, and if you will kill them young they will then be in perfection as to quality, while the increased size of the breed will cause them to be larger than the mongrels quite full grown, and consequently tough. There are as good Dorchings bred in Yorkshire as in any part of England.

**LOSS OF BEES (C. Clara).**—The fact that your two old hives filled supers this season is pretty good evidence that their bees were not lost from want of food, or driven from home by foul brood. No one can say with certainty what was the cause of the loss of the bees of both your old hives. They might have swarmed unseen, and lost their young queens afterwards on their marriage tours, an occurrence not at all unusual; or their queens may have died of old age when there were no eggs in the hives. More probably, succors were reared and lost in going out to meet the drones. When hives lose their queens from any cause their bees are often so disconsolate and disorganised that they do not attempt to defend their stores, and rapidly dwindle away and die. Doubtless the bees of your cast or swarm were so reduced in number by hunger before you began to feed them that they could not be preserved alive by feeding.

**BEES NEAR NOTTINGHAM (W. T.).**—We are sorry to learn that all your bees were drowned by the late floods. Nottingham is an excellent county for bees, and we think they would do well on the skirts of the town. The fruit trees of gardens yield much honey to bees; after the fruit blossoms fall bees find more honey in fields and forests than they do in gardens. If you cannot find a more elevated spot than your present garden on which to place hives, they may be kept and do well in the lefty house you propose erecting for them.

**POLLEN-CARRYING IN NOVEMBER (A. B.).**—Bees carry home pollen in fine weather as long as they can find it. Even Christmas Roses yield some of it to bees. Your bees working now is a sign of health, not of foul brood. The price of a good stock hive in spring is about £3; small old-fashioned hives may be had of cottagers at a less price.

### REMARKS.

10th.—Wet and stormy early; very dark for a short time about 8.30 A.M., then cleared and sun shining by 9; sun and cloud alternating all day, but heavy rain at night.  
11th.—Rain in night and early morning; fair at 9 A.M. and all day, but rather dull.  
12th.—White frost early; a pleasant frosty day; very fine till sunset, then rather foggy.  
13th.—A thoroughly wet morning, rather less so in the afternoon; but high wind and heavy rain at night.  
14th.—Very windy and rainy all day.  
15th.—Slight frost, but very fine all day.  
16th.—Fine morning, but rain soon after noon; showers during the afternoon; very heavy rain during the evening; fine at midnight.  
Extreme oscillations of barometer, and frequent heavy rain; ground saturated and air very damp.—G. J. SYMONS.

### COVENT GARDEN MARKET.—NOVEMBER 17.

Now that the glut of Grapes is over prices begin to mend. A cargo of St. Michael Pines has arrived during the week direct from the island in very good condition, and are being sold at reasonable prices. Pears consist of Marie Louise, Glou Morceau, and Crassanne. Kent Cobs are realising better prices.

From observations taken near London during forty-three years, the average day temperature of the week is 43.0°; and its night temperature 33.9°.

From observations taken near London during forty-three years, the average day temperature of the week is 43.0°; and its night temperature 33.9°.

## MUSHROOM-GROWING.

**I**F I were asked what it is which causes the greatest number of sleepless nights to the professional gardener I should say, Mushrooms. Yes, many of us have had Mushrooms on the brain for weeks together, for we are sure to have them there when they do not grow in the beds, and sometimes with all our care and attention to every little detail they will disappoint us. The spawn may run beautifully and the surface of the bed may look as if covered with myriads of homeopathic globules, and promise in a short time to supply us with Mushrooms by the basketful; but, alas! from some mysterious cause our hopes are never realised, and we are almost tempted to give up in despair. This happens at times to the most practical growers after years of unbroken successes. Let no one be surprised, then, at an occasional failure, for such a thing happens occasionally with all of us. I will endeavour to point out some of the weak points of the ordinary Mushroom-grower. It is an easy matter we know to have abundance at times—anybody can manage that—but to have a supply every day in the year, as is required in all large private establishments, is not so easy.

I have read in old calendars and nurserymen's catalogues directions for making-up beds in September to last all through the winter, and in February to last all summer, but I was never so fortunate as to have such accommodating beds; sometimes one will keep on bearing a little for three or four months, but this is the exception, and they can never be depended on to last that time. On an average, perhaps they last five weeks. In the spring and autumn they often last longer than they do in winter and summer.

To insure a succession I make up a small bed every three weeks; this generally keeps two beds in bearing. It is best, I think, not to have all the eggs in one basket; there is always an excuse for having too many, but no excuse for having none. The commonest mistake made, I think, is in exhausting the droppings too much before making-up a bed; they are heated and turned and heated and turned again, and the steam may be seen rushing away as if from a locomotive. This is downright waste. The steam is caused by the combustion of gases, which ought to be retained as much as possible for growing the Mushrooms, and the more there is consumed in this way the less satisfactory will the beds be. If Mushrooms from such exhausted material are produced at all they will be thin and leathery, or the crop will be scanty. Provided the beds when made up are in the right condition as regards moisture, and they do not heat too violently, the fresher the material is used the better. Mushrooms are always Mushrooms I know, but there is a surprising difference in the quality of them according to the method in which they are produced.

The best way I have found for making the most of the material is to have the droppings perfectly fresh, and

with these mix as much dust-dry soil as will absorb all superabundant moisture, breaking them about well with the fork at once so that the soil can be thoroughly mixed with them, and then leave all spread thinly in an open shed till required for use, never allowing them to heat much till made up in the bed. Practice alone can determine the quantity of soil to be used; it will often require fully a third part. The beds when made should not heat too much or they will burn themselves dry; 100° for a few days will not harm them, and as soon as the temperature is seen to be declining the spawn should be inserted in the ordinary way. 90° is not too high for spawning, provided we are certain the heat is subsiding. When down to 80° the soil should be put on, and in a few days afterwards a covering of dry litter or something else which will keep the heat of the bed up to about 75° for a fortnight; after which it may gradually fall to about 60° when the beds are in bearing.

Beds will come into bearing much quicker when the material is used fresh as I recommend. I have gathered Mushrooms in three weeks from the time of spawning, and the beds are seldom longer than five weeks before they are profitable.

The atmospheric temperature best suited for Mushroom-growing is an almost fixed one of about 55°, and a great deal depends on the way this temperature is kept up. It is best done without fire heat if possible, and for this reason a Mushroom house should be built so that it is not much affected by the outside weather. This is no doubt the secret of the success attending the growers of Mushrooms in the caves about Paris, that they are independent of outside weather. If Mushroom houses must be built above ground they should be constructed with hollow walls and hollow roofs, and the windows, if there are any, should be double-glazed. The outside air will not then have much effect on the temperature of the house, and the warmth from the beds will generally be sufficient for all purposes.

In summer we succeed best with the beds outside against a north wall. The other details of my management are similar to those of others growers, and it is therefore, I think, unnecessary to say more about them. —WILLIAM TAYLOR.

## DELPHINIUMS.

AMONGST the garden flowers which have of late years received consideration from the hybridiser there are hardly any more deserving of notice than the stately herbaceous Larkspurs. They are of a colour rare amongst garden flowers, blue; for while we have an abundance of scarlet, pink, yellow, &c., our blue flowers are, comparatively speaking, few. They are perfectly hardy, and will thrive in any ordinary garden soil, although, like most plants, doing best when it is of a kindly nature. Then, in addition to their first bloom, if they are not allowed to seed they will throw up fresh shoots if cut down; and many of the side sprays from these make effective flowers for mingling with others

in vases, bouquets, &c. Their culture is of the simplest character, and they soon make large stools, which had better be occasionally lifted and divided, an operation best done in early spring. But let the cultivator beware of snails; the young shoots, when they are just peeping above ground in early spring, form a delicacy for the whole tribe of slugs, and therefore it is very desirable to keep the stools well surrounded with soot and lime, and to have a sharp look-out at night for the depredators. As the plants seed freely, those who have space and are so inclined will, by growing a few of the best varieties, be able to obtain a great number of varieties.

Having this year been with Mr. Lakin of Chipping Norton, an ardent lover of herbaceous plants, and at the nursery of Mr. Ware of Tottenham, and having grown a selection of Mr. Laing's and noted some of the best, it may not be unacceptable to some of the readers of the Journal if I subjoin their names and a short description of each, dividing them into double and single sections.

#### DOUBLE.

*Alpeucuroides*.—A singular foxbrush-looking flower with a very closely set spike of greyish-blue flowers. Effective but not graceful.

*Argus*.—Dwarf, with flowers of azure blue and suffused slightly with violet, especially at the edges.

*Barlow's Perfection*.—Large spike, very brilliant blue, and flower closely set on the spike.

*Eugène Mezard*.—Fine compact spike of large size. Flowers blue and rose with white centre.

*Eugène Verdier*.—Ranunculus-shaped flower; blue and violet with starry white centre.

*Herman Stenger*.—Very fine; violet and blue with white centre. About 4 feet high, and a very striking plant.

*Keteleeri*.—A very large, bright, sky-blue flower.

*Le Mastodon*.—Bright blue; an immense flower, centre light. Fine spike.

*Louis Fiquier*.—Semi-double; rosy violet and blue.

*Madame Henri Jacotot*.—Light azure blue. A very fine flower of brilliant colour.

*Triomphe de Poissy*.—Ranunculus-shaped flowers of clear blue. Very fine.

*Victor Lemoine*.—Beautiful light blue, with lighter centre; petals imbricated. Very attractive.

#### SINGLE.

*Belladonna*.—One of the loveliest blue flowers grown. Unapproachable in its peculiar hue by any other garden flower; reminding one more of the beautiful *Vanda cœrulea* than of anything else. The smaller sprays are much coveted for bouquets.

*Formosum*.—An old but very effective flower, and well deserving a place notwithstanding the large number of newer varieties.

*Gloire de St. Maude*.—Dwarf, large flower; blue and black. Effective.

*General Ulrich*.—Cobalt blue shaded with bronze. Fine.

*M. Rivière*.—Violet red shaded white. Quite distinct in colour and very beautiful.

*Marquis de St. Innocent*.—Sky blue and lilac, white centre. Very distinct.

*Wilhelm Pfitzer*.—A very fine bright blue flower. Striking in colour.

With these, or indeed a selection from them, I do not think any cultivator will be disappointed.—D., Deal.

### HYBRIDS RAISED BY JAMES VEITCH & SONS.

GREAT indeed has been the enterprise and success of hybridists during this our day and generation. Fruits, flowers, and vegetables have been increased in numbers and improved in character to an extent which has no parallel in past times. Genus after genus of plants has been taken in hand, and from them are evolved new beauties—hybrids, as it were, of art and nature. Ever and anon the horticultural world has been startled by a fresh "break," a brilliant success it may be, of *Coleuses* and *Dracenas* by Mr. Bause, or *Clematises* by Mr. Jackman. These are all great achievements, and stand out in bold relief by the nature of the plants, their striking colours and undoubted usefulness.

But there are other evidences of lifelong work of the same nature in which the minutest care, the greatest manipulative skill, and extreme patience have been exercised before the results have been seen and success has been recognised. The

fruits of these labours, too, have necessarily appeared at intervals more or less remote, and their aggregate value was consequently not seen to the fullest advantage until Messrs. Veitch & Sons submitted the wonderful collection of plants which were worthily awarded a gold medal on the 10th inst. by the Council of the Royal Horticultural Society. This remarkable group merits special note alike by the intrinsic excellence of the plants, and many of them as being the first creations in their genera of the hybridiser's skill.

It is now nearly twenty years since Mr. Dominy received the medal of the Devon and Exeter Botanical and Horticultural Society for the first hybrid Orchid which had ever been raised, *Calanthe Dominii*, and almost every year since has brought out some new gem surpassing the last, and future years will give birth to newer forms which have not yet unfolded their characters. Orchids are not everybody's plants, they cannot be seen in every house and market; yet even of these one at least has become indispensable to all collections of winter-flowering stove plants, *Calanthe Veitchii*. This plant is not only distinct in its beauty, vigour, and free-flowering properties, but is remarkable as being a "mule," the results of fertilising *C. vestita* with *Limatodes rosea*. There are other results of noteworthy and unusual alliances, as *Phaius* and *Calanthe*, *Goodyera* and *Anacostichilus*, *Azalea* and *Rhododendron*, and *Lapageria* and *Philexia*.

This firm was the first to succeed in raising hybrids of *Nepenthes*, *N. hybrida* being the forerunner of other distinct varieties. *Cattleyas* were made amenable to artificial fertilisation, resulting in a family of unequalled diversity and beauty. *Cypripediums* have also yielded a rich harvest; and *Aërides*, *Lælias*, and *Dendrobiums* have not been proof against the hybridiser's skill. Here it was that the first "break" was made in the *Dracenas*, and here also, to coin a term, originated the *Azaleo-Rhododendrons*.

As an instance of the patience needed in raising plants included in this list, is the fact that *Nepenthes*, *Calanthes*, and *Cypripediums* are three to five years, *Aërides* ten to twelve years, and *Cattleyas* five to fifteen years, before they bloom after the seed is sown; and the constant watchfulness and care in nursing into life and to perfection plants of this nature is a tribute to the perseverance of the raisers that can hardly be appreciated by the outside world. The extraordinary list of plants now noted are an honour to the famed establishment of the Messrs. Veitch, as they are a splendid example of the power and influence of hybridisation. As being the productions of one firm they are probably unequalled in the annals of European horticultural enterprise. Their names and parentage are submitted. The list alone is eloquent, especially when considering the nature of the plants which the firm has been operating on for a quarter of a century.

## FRUIT CULTIVATION AND MANAGEMENT IN KENT.

At a meeting of the Institute of Surveyors held at 12, Great George Street, Westminster, on the evening of Monday last, G. Webb, Esq., of Tunstall near Sittingbourne, read the following paper on fruit cultivation and management in Kent. The chair was occupied by Thomas Huskinson, Esq., the President of the Institute.

So many able papers on matters of interest and importance to surveyors have been read in this room, that in appearing before you to treat of fruit-planting I feel that I have undertaken a task which I can hardly hope to accomplish as I should desire. I should not have ventured indeed to approach it at all were it not for the hope that other members, by their greater knowledge and experience, may be able to make up for my deficiencies. I am obliged also to confine my observations to Kent, as I have seen very little of the orchards in other counties.

It is hardly more than twenty years since railways first opened out our county, but during this short period the cultivation of fruit has received greatly increased attention both at home and abroad. Where soil and climate are favourable new fruit plantations are to be seen springing up in all directions; fruit-growing begins to figure prominently among the industrial resources of the kingdom, and a great question must soon arise whether the consumption of our increasing population will keep pace with the supply afforded from so enlarged an area of planted land. This year has probably been the best for many years past to test the question, for the crop of all kinds, more especially of Cherries, has been enormous; but I believe that if the rainy season had not prevented the gathering, the greater part of this heavy crop would have found a remunerative market in the manufacturing districts. From the returns of 1874 the fruit crop in England is stated as occupying, excluding gardens, 145,622 acres. The counties which contribute the largest acreage are Devon, 24,812; Hereford, 21,534; Somerset, 19,857; Worcester, 13,390; Gloucester, 11,152; Kent, 11,186; Cornwall, 4,180. No other county has 4000.

Now, we cannot be surprised that the study of fruit, whether the object be pleasure or profit, should more and more attract the attention of our countrymen; for the interest attaching to its culture never ceases, and there is no period of the year unrepresented by some fresh source of delight or interest. Even in winter, after the trees are stripped, we eagerly watch to see what fresh wood has been made; what are the prospects of fruit buds, and what further pruning is required; but apart from purely pleasurable associations I shall be able to show you that good returns have been realised by those who have

spared neither pains nor expense in the cultivation of their fruit land.

Now, before speaking of fruit plantations, I ought to say a few words as to the preparation required in making fresh orchards; for everything depends on a good start. The first thing to be done is to select the ground. If it be possible to do so, avoid all low-lying lands or valleys, for valleys catch the frost most; and take the higher land, having a south-east, south, or south-west aspect. The more trees are exposed to the east the better, for the morning sun in such situations comes out gradually on the bloom; whereas, if the sun (after having been up some time) falls suddenly on the trees in valleys, the bloom is certain to be cut off. We had a marked instance of this in the severe frost of May, 1871. One orchard lay in a valley, with rising ground to the west, and the bloom was not only completely cut off, but the trees themselves were so injured that they took three years to recover; but where the land was only 12 feet higher the frost took very much less effect. Shelter on the south-west is very desirable, either by means of a good high Quick hedge or a belt of Larch, as westerly gales do much injury to both fruit and trees.

Before planting, the land should have a dressing of well-rotted compost. It should then be deeply ploughed and subsoiled or dug, and trenching, although expensive, always pays. The field should then be properly squared and set out; the holes for standard trees well thrown out, not less than 8 feet over by 2 feet deep (for which we pay about 4s. per 100), and, if possible, every tree should be planted by the 10th of December. The depth best suited is, say, from 6 to 9 inches. Young trees should always be carefully watched during the summer after planting. The moment the leaves droop the water-cart should be employed; or, where this cannot be done easily, some rough farmyard dung should be put round the trees to keep in the moisture. In exposed situations, or where there is stock, the trees will require some support for protection. Five or six old dipped hop poles or stakes bound with a piece of iron hooping at the top make a good guard; or, against sheep or rabbits, tree guards cut from common wire netting answer well. After the tree is once started the pruning knife must be freely used for the first three or four years to form a good head, and the shoots will require to be both shortened and thinned. It is better to clear the inside of a tree while young than after it is old.

Next comes the great question, What to plant? It is, of course, most important to select the sort of fruit and the kind of cultivation which specially suits each locality, for herein rests future success or disappointment. The questions of soil, climate, aspect, and the description of fruit best adapted to them must be deeply weighed and considered; and after all this is done there still remains another difficult consideration—namely, Covent Garden Market. We must please our customers and must keep pace with the times, or all our care and skill in cultivating will go for nothing. The popular sort of to-day may in three years' time be entirely discarded; and then will come all the mortification of having to replant or to re-graft, and a great loss of both time and money. In showing the necessity of studying climate, I cannot give you a better illustration than the Ohaumontal Pear. In Jersey these Pears grow on the bush, and are so fine that they frequently sell for 1s. each. In Kent, about 100 feet above the sea level, this sort bears well, and two years out of three is well flavoured; but at an increased altitude of 800 feet the fruit is no better than a Turnip.

Again, as to the study of the market. The sorts that often engage the attention of the grower are by the fruit-salesman or cotermonger the most neglected. The latter wants an Apple or Pear that will last beyond a day, and which will preserve its colour and quality. Pears such as Williams' Bon Chrétien, Beurré Boe, and Beurre de Capiaumont are the kinds which answer their purpose best; but fine showy sorts like the Beurré d'Amanlis, Colmar d'Été, and Gratioli they care little for. That useful and early Apple the Keswick Codlin formerly sold well, but now, from being so plentiful, hardly pays expenses of sale.

I now proceed to treat of fruit plantations under three different classes:—1st, Orchards planted entirely with standard trees, the bottom being grass, fed-off by sheep. 2ndly, Fruit plantations containing standards or half-standards, with which is raised a plantation of Gooseberries, Currants, nuts, &c. 3rdly, Fruit plantations which grow bush fruit, and of the berry tribe only. I may here state, that by the terms I mean to include Gooseberries and Currants, both Red and White.

While dealing with these classes I propose to refer to the sorts of fruit most applicable to each kind of cultivation.

Orchards are, perhaps, the most desirable on the whole, for the reason that they require less labour and last longer; nor can anything exceed the beauty of an orchard when in full bloom; for the effect of the snow-like blossom, aided by the greenward beneath, is most charming. The plan now usually adopted is to set the permanent trees of Cherries, Pears, or Apples 10 yards (or where the land is very strong, 12 yards) apart each way, with a Plum as an intermediate plant. The Plum is the plant generally selected, as it rarely lasts longer than the time required for the other sorts to get up. This gives eighty trees to the acre.

As a native of East Kent I may, perhaps, be excused for commencing with the Cherry, which, I believe, was first introduced into our county. Hasted in his "History of Kent," under the head of "Tenham (or Teynham)," says, quoting Lambarde, "That this parish with thirty others lying on each side of the great road from Rainham to Blean Wood, was in his time the Cherry garden and Apple orchard of Kent, and such it undoubtedly continued to be till within memory. It was the parent from whence the other plantations issued, for Richard Hayns, fruiterer to King Henry VIII., having observed that those plants which had been brought over by our Norman ancestors had lost their native excellence by length of time, and that we were served from foreign parts with these fruits on that account—which he saw no reason for, as neither the soil or climate here were unequal to the bringing of them to perfection—determined to try a plantation of them here; for which purpose having in 1538 obtained 105 acres of rich land, then called the Brennet, and having with great care, good choice, and no small labour and cost, brought plants from beyond the seas, he furnished this ground with them in rows in the most beautiful order. These fruits consisted of the sweet Cherry, from hence usually called the Kentish Cherry; the temperate Pippin, hence for the like reason called the Kentish Pippin, and the Golden Benet." Mr. Furley in his "History of the Weald of Kent," also records that Camden, following Lambarde, describes Kent as abounding in Apples beyond measure, as also with Cherries, which were brought out of Pontus into Italy 680 years after the building of Rome, and 120 years afterwards into Britain (A.D. 48). Mr. Furley also observes that Fuller, who published his "Worthies" in 1662, states that one of the orchards of this primitive plantation consisting of thirty acres, in one year produced fruit which sold for £1000. As Mr. Furley justly observes, "It may be doubted, looking at the difference in the value of money, whether our modern cultivators can surpass this return." But to proceed. Cherries like a dry subsoil and will not do in the clays, neither do they like cultivation for any length of time; and although the trees will attain a good size and bear at times tolerably well, they do best on grass, and when their roots are undisturbed. Plantations of Cherries are, however, frequently raised on cultivated land with a crop of underfruit, and the trees will in this way make wood very fast. After eight or ten years, however, the land should be laid down to grass. A good climate is indispensable for Cherries, especially such sorts as the Bigarreau and the Duke tribe. These sorts flourish best at an elevation of from 80 to 900 feet above the sea level; Black Heart, Kentish, and Turkey Hearts will do fairly up to 400 feet; but at any elevation beyond this the chance of a crop is very precarious, and the fruit is indifferent. It is odd that although our great propagators have added of late years so many excellent and useful varieties to the stock of Apples, Pears, and Plums, yet with Cherries we have had but few additions. The old recognised sorts continue to hold a prominent place in all fresh planting. We much require a few good early sorts to compete with the foreigner; but what new sorts we have must be proved before we know their standard qualities. For all useful purposes I should recommend for orchards—

Early Purple Gean  
Adams' Crown  
Frogmore Bigarreau  
May Duke  
Governor Wood  
Cleveland Bigarreau  
Elton  
Knight's Early Black  
Old Black Heart  
Walsley  
Bigarreau

Mammoth  
Mary  
Black Tartarian  
Black Eagle  
Flemish  
Turkey Heart  
Florence  
Kentish  
Cluster  
Morello

The above will ripen in the order in which they are placed.

The Bigarreau, and Cluster, make the largest trees; indeed, the latter might be planted as an ornamental tree in any park. It is of no unfrequent occurrence to obtain from eighteen to twenty-five sieves of 48 lbs. each from a Cluster. Mr. Neame of Selling Court has sent to market forty and a half sieves from one tree (nearly a ton); but what is quite as wonderful, I have known a tree at Milton which has grown twenty sieves of Adams' Crown. Cherries where they thrive as a rule pay well. In letting an estate some fourteen years ago, where it was incumbent on us to make the most we could of the property, we decided to reserve the fruit and let the bottoms. There are about ninety acres of mixed fruit, principally Cherries. The fruit has been sold by auction when fit to gather. I give you the return of these orchards, together with some others which come under our notice and management. The expenses of sale are not taken off, but may be taken at about 2 per cent. The bottoms are let at about £2 per acre, and an allowance is made to the tenant for a proportion of rates and tithes.

Name of Parish.	Number of consecutive years the fruit has been sold by Auction.	Average.		Annual average sale for the years stated in the column 3 of		Total average sale of Cherries and Hard Fruit.		Average Return per acre for years stated.		Remarks.
		A.	P.	Cherries.	Hard Fruit.	£.	s.	£.	s.	
Orchards.	14	66	0	1814	500	1714	0	10	9	15 acres of these have not arrived at perfection. Old plantations.
Ditto	15	80	0	880	250	600	0	20	14	The same.
Ditto	15	88	0	488	140	578	0	17	19	This orchard has low and flat.
Ditto	15	10	0	60	60	127	0	13	14	An old plantation; has well.
Ditto	15	8	80	88	6	94	10	84	7	Sold privately to gather.
Ditto	5	9	0	—	—	970	0	80	0	The same.
Ditto	4	7	0	—	—	928	0	57	0	

The plan of selling by auction is an easy one for the grower, and, on the whole, we find that the trees are fairly taken care of. I find the cost of gathering and marketing Cherries to be about 8s. per sieve, which is an increase of about 1s. compared with twenty-five years ago. We calculate that we have made on the trees for the last ten years an average of 5s. 6d. per sieve.

I next pass to Pears, which require a deep rich soil, and of the two a better climate than Cherries; but they are not so

much grown in Kent as the latter. The sorts principally grown for profit are—

TIME OF RIPENING.	TIME OF RIPENING.

Joséphine de Malines ..... Feb. and May.	

Plums are grown in our orchards merely to fill up intermediate spaces between other trees. They never make very large heads, and consequently are more suited for confined spaces; neither do they last so long as Cherries, Pears, or Apples, for the wind has great effect on them, and when they attain to any age they lose large limbs. Their roots skim just under the surface, and they consequently soon derive benefit from any dressing of manure. Not long since I measured the distance which some Plum roots had travelled from the main stem, and found it to be 46 feet. There are some orchards in Kent planted entirely with Plums, generally 6 by 7 yards apart, and they are very productive, notably one of Green Gages at Gillingham. A few years ago this piece was a perfect model of a fruit plantation. The trees were large for Gages, and bore abundantly in one year, making, I believe, more than £100 per acre. The trees are going off now, but there is an intermediate plant of other kinds coming up. The owner was offered £250 an acre for the fruit on the whole 28 acres, half of which was not nearly so valuable as the Green Gage part.\* Green Gages are so useful for domestic purposes that it will be a long time before we have too many of them.

The best sorts for bearing, and the kinds possessing the most useful qualities, are—

Early Rivers	Sandall's
Early Orleans	Prince Engelbert
Dauphine	Washington
Victoria	Mitchelson's
Belgian Purple	Autumn Beauty
Stone Wood	Diamond
Orleans	Green Gage
Gisborne's	Online Golden Gage
Goliath	Jefferson
Belle de Louvain	White Magnum Bonum
Fond's Seedling	Cinder Damsen
Prince of Wales	Prune Damsen

Lastly I come to the Apple, the most useful of all fruits

both to the rich and to the poor. For eleven months in the year this excellent fruit supplies our tables; but although cultivated largely in certain parts of Kent, we find, as a rule, that Cherries pay better where the soil is suitable. Apples will grow on almost any soil, even on stiff clays, if drained, but they are not so suitable for orchards, as the grass grows more rankly, and the sheep as a consequence do not feed so closely. Where the soil suits, the Apple makes a large head and requires as much room as any tree. I have heard of 500 bushels being grown on one acre. As for sorts their name is legion, but some of the best are—

I next come to fruit plantations which have standards or half-standards, and underfruit. The plan generally adopted is to plant the trees, which are more frequently half-standards, 22 feet by 16½ feet, with Gooseberries or Currants between them 5½ feet apart. The cost of the trees, bushes, and labour comes to about £20 per acre. In about three years the berries will begin to bear and to make some return. Trees grow faster and bear sooner in arable plantation than on grass. The cultivation assists very much, and of course the more the land is manured the greater will be the crop. Apples, Pears, and Plums suit this class of planting best. Large returns are made by the underfruit, especially if the plantations are near towns or railways, an acre of berries frequently realising from £20 to £30; indeed, a large grower near Maidstone informed me that he had made £100 per acre from one piece of Gooseberries; this was, of course, an exceptional price. The sorts most used are the Golden Drop, Whitesmith, Rifleman, Crown Bob, Lancashire Lads, Velvets, and Warrington. Black Currants also are now attracting much attention. They require a strong stiff soil. The sale of this fruit has increased much of late years; some say to make port wine, others for use as a dye; however, the fruit is one of the most wholesome we have, and makes an excellent preserve. The Baldwin's Black is a great improvement on the old sort, but I am not certain whether this and the Naples are the same. I have seen trees lately which have borne as much as half a sieve each, and one planter in Rainham told me that he had grown 250 bushels on 2 acres at three years old, and realising £118 less the expenses of picking and sale. In West Kent, especially on the ragstone, Filberts and Cob Nuts are more grown than berries. The soil exactly suits them, and they bear most abundantly. The Cob Nut is, however, fast taking the place of the old Filbert, being found much more productive and profitable. The Nut is larger, but not so well-flavoured as the Filbert; but it grows much quicker to bearing. I have seen some trees at Loose, near Maidstone, which grew 40 lbs. on a tree, and over £100 per acre was made of one particular acre. The trees are generally planted about 16 feet apart each way, and the pruning of them requires considerable skill and care. For this work the usual price ranges from 2d. to 3d. per tree.

Plantations used for Berries only.—These plants are generally intended to remain for a few years only, with a view to temporary profit. This plan is the best, as the upper fruit is raised while the under fruit is bearing. Gooseberries and Currants are generally placed 6 feet apart each way, making 1210 plants to the acre. The cost ranges from 8s. to 16s. per 100. Many growers (especially with Black Currants) now

\* There is also another orchard of 8 acres, all Plums, near here, the trees planted about 18 feet apart. This has realised by auction £25 per acre on an average of the last three years.

plant an intermediate bush, which is taken out again after five or six years. By this plan they obtain a better return at starting. It is now found much better to form the young Black Currant as a stock instead of a bush. This is done by not taking off any of the buds when the cuttings are struck. The plant in this way forms a better head and lasts many more years. In all kinds of plantation it is most essential to have a man who thoroughly understands pruning, as the amount of produce is more or less dependent upon the intelligence of the cutter. As a rule, the young gardeners of the present day do not attend sufficiently to the art of pruning. They ought to have proper training at the nurseries before they undertake such responsible work. My experience is that not one in ten (even among professed gardeners) thoroughly knows his business. For educational purposes I can recommend M. Du Breull's book on pruning as a good practical work.

The drawback to fruit plantations which are under cultivation is the great cost of labour in keeping them clean; for if roots and weeds are once allowed to gain the upper hand the expense of subduing them becomes enormous. As the fruit-picking season comes on labour gets scarce, and there is great difficulty in getting work done.

Our fruit plantations have all been dug well once over, many twice, and have had at the least four hoeings, yet I should have been very much ashamed if any of you had seen them last August.

In West Kent on the light soils and shingle both Raspberries and Strawberries are cultivated to an immense extent, and very profitably; but this is a class of fruit we have not time to discuss. I can only remark, as showing the progress of fruit cultivation, that in the space of about twenty years probably not less than one thousand acres of poor woodland about Farningham, the Crays, and Sittingbourne have been grubbed, and are now growing fruit of this description, or of the other kinds I have enumerated.

There is another kind of cultivation of dwarf fruit which, so far as profit is concerned, may be considered at present to be in a state of infancy, but which I believe will command great attention presently. I allude to the growing of the Apple on the Paradise or Doucin stock on bushes—the effect being the same as growing the Pear on the Quince, or the Cherry on the Mahaleb stock. The object is to avoid profuseness in growth, so that quicker results and greater bearing propensities may be obtained. Many of our amateur fruit-growers have already done much to assist and encourage this most interesting class of fruit-growing, and I believe, when well understood, we shall find the system to be very profitable. The great benefit is, that by this mode of culture anyone possessing even the smallest plot of ground can have a succession of fruit. These dwarf trees can be planted 3, 4, or 6 feet apart at first, and thinned as they grow too large; therefore any person having only 6 perches of land might have one hundred trees. Mr. Rivers in his useful work "On the Culture of Pyramid and Bush Fruit Trees" has so well described the treatment required for dwarf fruit, that I cannot do better than advise you to study his work. Our countrymen owe that gentleman, Dr. Hogg, Mr. Scott of Merriott, and many other propagators, their thanks for the great services they have rendered.

I must conclude my paper with a few remarks on old orchards and fruit plantations, because we must all have observed that many such are much neglected. It is no uncommon thing to see trees running into one another owing to the planting being too thick, or from profuse growth. Now a little thinning or shortening of the lateral branches will do great good. There should not be less space than 8 feet between the boughs of every tree, so that a ladder may be worked easily, and the sun and air let in; but large boughs (unless dead) should never be cut off if it can be avoided. It is often the custom to cut and thin out the inside of old Apple trees, but great injury is done by the practice after the trees have arrived at any age. A very good fruit-grower once remarked to me that he liked the interior of his Apple trees to be so thick that he could not see to shoot a partridge through them, and I quite agree with him, for we once had the greatest injury done to an old plantation of Apples by the clearing-out of the inside of the trees. The plantation had borne 3500 bushels in one year, and the next year my father was advised by the bailiff to have the trees trimmed out. The remarks of the man appeared reasonable enough. He urged that we could get no fruit inside but a few scrubby Apples, and that what went to support these

boughs would help the other parts of the tree. The work was allowed to be done, but the result was most disastrous, as nothing like the same quantity was ever grown again. I believe manuring never pays better than when bestowed on old plantations. The treatment appears to give fresh vigour and bearing power to old trees if they have any good wood left. It is not, however, always necessary to manure with dung, for feeding sheep with corn or oilcake answers much the same purpose. I end by advising everyone to have each tree looked to and examined early in the autumn, and never to allow an unproductive one to remain or be regrafted.

## THINGS NOT GENERALLY KNOWN.

### ACACIA.

I do not think it is generally known that there is no wood lasts so long for posts as Acacia. There is little or no sap, and it lasts underground far longer than Oak. If sown and transplanted and cut down from time to time like Ash, it grows very quickly from the root or stool, and makes very durable Scotch fencing. More persons ought to turn their attention to planting it in covers. It is not a tree that attains to a great age or size, as it quickly matures.—C. P. P.

LOUGHBOROUGH CHRYSANTHEMUM AND FRUIT SHOW.—A Committee of the leading horticulturists, with the Rev. J. Bird as President, has lately established a Chrysanthemum Society, and have just held their first Show, which was a very successful one. Notwithstanding the unfavourable season, this new Society has produced an excellent show of this favourite autumn flower; and, judging from the spirit displayed, Loughborough will soon become as eminent for the growth of the Chrysanthemum as it is for the growth of roots and vegetables. Very fine-trained specimens of both large and small varieties were staged, and the cut blooms were such as to call forth remarks of astonishment. The show of winter fruit was particularly good, and every prize was sharply contested.

## NOTES AND GLEANINGS.

A GENERAL Meeting of the Fellows of the Royal Horticultural Society will be held at South Kensington on Thursday, December 9th, at three o'clock P.M., to receive from the Council an explanation of the Scheme of Privileges for 1876, and to give an opportunity to the Fellows of stating their opinions on its details. The attendance of the Fellows on this important occasion is most desirable.

— MESSRS. CARTER & Co. of Holborn have offered a series of prizes for vegetables at the Shows of the Royal Horticultural Society in 1876, amounting in all to £78.

— THE next dinner of the HORTICULTURAL CLUB will be held at the Club House, 8, Adelphi Terrace, on Wednesday, December 1st, at 6.15. Members have the privilege of introducing a friend. It is particularly requested that instruction be given to the Secretary by the 29th inst., as much inconvenience was occasioned on the last occasion. Double the number of members expected were present, and although the resources of the Club are considerable, it is not easy to alter tables on so short a notice. A card to the Secretary would be sufficient.

— WE are informed that the ROCKWORK at Sandringham, Dunorlan, Battersea Park, and Osmaston, which have been praised in our columns, were all erected by Mr. Pulham of the Stoneworks at Broxbourne.

— OUR foreign imports of CHESTNUTS have been declining; they have ranged from 65,000 bushels to 25,000 bushels. Chestnut flour, so unknown to us in England (although there is no reason why this should be), is the staple food of many Italian peasants, with which they make their polenta, preferring it to Maize, as being more nutritious. The cost per head for this kind of food is from 8d. to 4d. per day.—(Food and Fuel Reformer.)

## GRUBS DESTROYING VEGETABLES.

SOME years ago I could not, and had not, grown any tap-rooted vegetables fit to cook, when one day to a gardener who came from a distance to see my Carnations I told the difficulty I was in. He said, "At the back end of the year put on

a thick layer of spent gas lime, and in spring dig it well under, and you will have all the vegetables you can wish." The result was, we had more than we could use and the finest in the country round. I allude to Cauliflowers, Cabbages, Carrots, Onions, Beets, Parsnips, &c., and some of which were finer than I have ever seen since. I left the house in the following year, but the succeeding tenant corroborated some years after what I have now written.—J. C.

### KEEPING GRAPES FRESH.

THE accompanying sketch (fig. 98) is of a tin tube 2 inches diameter at the top and about 8 inches deep, which will hold four bunches of Grapes; the tube to be filled with water and a few pieces of charcoal. The top of the tube is to be fastened in the centre with copper wire; the ends of the wire twisted will form a loop to hang the tube from the edge of a shelf or any other method, so that the Grapes may not touch the wall.

I use small bottles for a single bunch, hung on iron rods with small hooks. The four divisions at the top of the tube keep the bunches at equal distances from each other. The bunches to be cut with 7 or 8 inches of wood, so that they may not slip out of the tube.  
—JAMES CROSS, 15, Devonshire Buildings, Bath.

**SEASHORE WEEDS ON GARDEN WALKS.**—Mr. Robson, on page 447, makes inquiries for something that will destroy seashore weeds on garden walks. If he can conveniently procure gas water I think it will destroy the weeds thoroughly. I always use it here, and I find it more powerful and lasting in its effects as a weed-destroyer than salt.—M. H., Coleorton.

### OLLA PODRIDA—A CONTINENTAL TOUR.—No. 7.

I HAD no idea when I began an account of our short tour on the Continent that it would occupy so much space in the columns of your Journal, and must, in this my concluding paper, apologise to your readers for having been so long in finishing these somewhat desultory remarks, which by the pressure of other matters I have not been able to conclude before.

It is my intention now to compare (even though, as Mrs. Malaprop said, "comparisons are odorous") Battersea Park with other parks and gardens abroad. Wishing, while other parks were fresh in my memory, to take a stroll through Battersea Park, I did so a few days after my return to London, and was much pleased with what I then saw. I especially noted as being attractive some varieties of the Fuchsia with ornamental foliage, such as Meteor, Pillar of Gold, &c., which combine both high-coloured foliage and graceful flowers. Mr. Rogers tries new varieties of Pelargoniums, Lobelias, &c., every year, but does not give them a prominent position till well tested. Among the Lobelias on trial were some new varieties from Mr. Henderson:—Charming, Unique, and Defiance of the pumila section—the latter is a lilac somewhat similar to Omen—and Brilliant is a good bright blue of the speciosa kind; but none of the Lobelias seemed to be better than a selected strain of pumila raised by Mr. Rogers himself, called, I think, maxima

assura. Planted alongside one of the drives were some trial plants of some of Mr. Pearson's best Pelargoniums. Mr. Rogers kindly put himself at my disposal, and met me near the lodge at the Battersea Road station end, and drove me round the principal drives, while we left the carriage from time to time to see more closely the more interesting part of the parks and gardens. I am not going now at this distance of time, having only made a few cursory notes, to attempt a full description of each bed and each design. I only wish to give my general impression of the park.

Now, first of all, I may observe that in point of position as well as in the general outline and landscape the park has had much to contend with, and much credit is due to those land-

scape gardeners, especially Mr. Gibson, who have so well overcome these natural difficulties.

A flat piece of ground with, I believe, hardly a rise or irregularity in it anywhere, lying close along the river, where it had to contend with spring frosts and damp, within reach, too, of the smokes and fogs of London—these, all gardeners will admit, are certainly difficulties of no slight nature, and yet the result is such that there are some portions, especially the subtropical and more highly-kept parts, which give as much or even more satisfaction to me than almost any gardens I know. This result has been accomplished by judicious planting, by careful study of the general outlines and contours of shrubberies and beds, and in the disposal of the proper trees and shrubs in the right places. The soil which was taken out to form the lake has been used to make raised ground for planting on; and the subtropical garden, which is one of the

Fig. 98.

most ornamental and successful features of the park, is protected by the manner in which these raised banks, carefully planted, protect the more tender plants from winds and weather. I do not say that the park is perfect, but the care with which it is kept, and the variety of plants and shrubs which are to be found, and the advantage which is taken of the different kinds of plants, hardy, alpine, herbaceous, bedding, subtropical, &c., each to produce their own effect in their own way, is an agreeable contrast to the want of care and attention in foreign parks and gardens. I do not wish to repeat my former remarks, but in the parks and gardens abroad too much seems to be left to the climate, and too little to art and cultivation.

I do not like at Battersea the attempt at imitating natural rocks with stucco and plaster. No one expects rocks there, and no one is deceived, and to the end of the chapter it will remain a mere mass of concrete, on which Ferns will not grow, and even Ivy will not cling, nor even, I believe, Ampelopsis and other plants. It would have been far better, I think, to have made a rockwork of stones and soil disposed irregularly, so as to have given different sites and aspects for Ferns, alpinas, &c., and to have studied the habits and requirements of the plants, than to have stirred up the wonder and admiration of the Cockneys by sham rocks in concrete. I believe, however, the intention was good, and I do not wish to be over-critical. The ornamental water, too, is still left too flat in its outline, though the general contour is good.

I am going to have, too, my growl about pin cushion beds and carpet bedding; and here I do not want my remarks to apply to Battersea Park only, where I do not think too much

space has been devoted to it, but to the general rage for lawn millinery and formal geometrical patterns entirely depending on foliage plants clipped by rule and measure, and constantly pinched to preserve a uniform and regular shape. No doubt a person may say, You mow your lawn to make a green carpet; you tie up plants to prevent them straggling, and art is always trying to control nature. This is true to a certain extent, and I do not wish to see this geometrical carpet bedding entirely excluded, but only judiciously limited. I remember I was once accused of wanting to see miles of scarlet Geraniums and yellow Calceolarias because I endeavoured to fight the battle of bedding plants, and affirmed that the system of planting beds with the most durable and perpetual-blooming half-hardy plants had done more than anything else to spread and to foster the love of gardening; but I should be very sorry to see flowering plants pushed on one side to make way for foliage plants of dwarf growth, planted merely for geometrical effect, and which do not vary, for this is one of their great demerits, in my mind, that there is such a sameness and monotony. Once go and see a geometrical garden well clipped and cared for, and you will see it just the same every day of the year after, I mean when it has once reached its best. It may vary a little between being a little less clipped or more clipped; sometimes the Golden Pyrethrum may have grown a little too rampant, or the Alternantheras, and Leucophytos were bedded too much with the rain, but the general monotonous effect is still the same. I know if persons will use the same kind of Geranium, or Verbena, or Calceolaria throughout a whole garden, and reckon the value of a bedded garden by the number of Mrs. Pollock or Lady Cullum, that the same monotonous effect may be produced; but no amount of foliage plants, however carefully tended, can, in my mind, make up for the want of proper varieties of flowering bedding plants judiciously selected. No doubt days and weeks of rainy weather are trying to the lover of flowers; but, then, what gardening pleasures are comparable to a carefully selected set of flowering plants when the weather is favourable? I do not wish, as I said in the beginning, to find fault with Battersea Park in particular on this score because these geometrical beds are there only introduced in their place, and not made the general *pièce de résistance*. The subtropical part, where advantage has been taken of both form and flower, and where plants are encouraged to develop and show their true nature, is what makes Battersea Park so really attractive. I was too early to see the real effect, but having seen it in other years when more fully developed I could judge what the ultimate effect would be.

I will not attempt at any length to describe the various arrangements. I was very glad, amongst other plants, to see the different Begonias, with their graceful scarlet blossoms, promising so well; the different kinds of Erythrina mixed with Abutilon; Grevillea robusta, and other foliaged plants, presented an ornamental contrast. The Jacaranda promised, too, to be a useful plant; and amongst other commoner plants, the Cineraria maritima compacta was effectively employed.

I will now glance at Mr. Pearson's Pelargoniums. These were friends (I was going to say old friends of mine, but that would not be strictly correct), but many of them were known to me. Among the best were Ethel and Miss Annie Orton—no relation, I hope, to the claimant, and certainly not so great an impostor—Brutus and Pirate, dark crimson; Sir H. S. Stanhope, a fine deep red; and Lady Stanhope, of the colour of Lucius or Excellent; Charles Smith, one of the very best of the new dark crimsons of the stamp of Edward Sutton or General Outram, and many others which I need not particularise. There were beds of Mrs. Turner and Mrs. Gibbons of the lilac-pink section which were much alike, and when so many good new sorts are now sent out it is difficult, of course, to make a selection and to decide which of the newer ones to propagate. One thing I am very well assured of—that the old favourites, such as Tom Thumb, Stella, &c., will gradually have to give way.

Cannas are extensively grown, and make an especial feature in many of the groups, but care must be taken lest they be used too much and in too great masses. The Cannabis gigantea, which was only just being planted out, is one of the most effective of all the subtropical plants, and Mr. Rogers told me he had had more inquiries regarding it than almost any other plant. Even here in the far north plants of it have grown from 9 to 10 feet high on a warm border, and 4 to 5 feet through.

Space warns me that I must conclude, and I can only add that such gardens and parks as Battersea, Regent's Park,

Crystal Palace, &c., conclusively prove to me that English gardeners are in advance of their brethren across the water.—O. P. FRACK.

### AUTUMN ROOT SHOWS.

ALTHOUGH not in the immediate province of a horticultural publication, yet farming is of kin to gardening, and in recognition of the enterprise of the promoters of the Shows and the cultural skill of the exhibitors of the roots, we will notice briefly the two great Exhibitions which have recently been held. Taking them in the order of priority of date, the Exhibition of Messrs. CARTER & Co. was held in the Agricultural Hall, Islington, on the 18th inst. The liberal prizes offered, amounting in the aggregate to nearly £250 including silver cups, brought out a much larger display than usual. The roots—of which there were thousands, in fact tons, occupied the entire north gallery of the Hall and also the west end of the building—were not more remarkable for the size of the specimens than for the distinct features of the different kinds, which instanced in a striking manner the purity of the stocks.

It is not the mere size of roots that we especially admire, neither perhaps do the cattle, nor have on this occasion the Judges; and we can imagine that in the great competition for the premier prize in the class for the "Imperial Hardy Swede" that some disappointment would follow, for the cup was awarded to Mr. Weevil for comparatively small roots but of unsurpassable quality. The hard iron appearance of this variety is worthy of its name, or the name is worthy of it, and it is evidently highly popular with agriculturists. The long red Mangold Wurtzels were enormous, but Mr. Ensor won with not the largest but the brightest and best. Prizes, however, were given for the "heaviest" in some of the classes, and one lot of three roots weighed 125 lbs. The greatest and best show of Globe Mangolds consisted of "The Warden," and Mrs. Norton had the premier prize. The exhibits in this class were specially admired for their uniform high quality. Turnips—white, purple, green, and yellow—were exhibited in great perfection, as were Kohl Rabi, Farnips, Carrots, Beet, Onions, and Potatoes, the collections of the latter from Mr. McKinlay, Mr. Cholmondeley, and Mr. Lumsden being of high excellence.

The best products of eight sewage farms were staged, and amongst the exhibitors who did not compete were Her Majesty the Queen and their Royal Highnesses the Prince of Wales and Prince Christian. The Exhibition was highly creditable to the great Holborn firm and their customers, and the awards showed great discrimination on the part of the Judges.

At one end of the Hall a collection of roots and vegetables of splendid colour and quality was exhibited as having been grown on poor soil by the aid of Amies' chemical manures.

MESSRS. SUTTON & SONS, READING.—I have now for some years chronicled the character of this grand root show, which every year seems like a schoolboy to be outgrowing its clothes. The Show was held on Saturday last, and as usual exhibitors of all grades were there, from the small tenant farmer up to Her Most Gracious Majesty the Queen. The Dukes of Portland and Sutherland; the Marquises of Anglesey and Bristol; Earls of Warwick, Harrington; Calthorpe and Camoys; while baronets and members of Parliament by the dozen entered the lists. As to the general character of the Show, one may say that there was a larger number of really excellent roots in the various exhibits than on any former occasion, while the roots of Sutton's Yellow Intermediate Mangold seemed to me to be best and prettiest portion of the farm produce. A few of the weights may not be uninteresting. In Suttons' Berkshire Prize Yellow Globe Mangold the heaviest lots weighed 299 lbs. (twelve roots). In Suttons' Mammoth Long Red the heaviest twelve weighed 440 lbs. Of that beautiful and valuable sort the Yellow Golden Tankard, twelve weighed 248 lbs.; but Suttons' Champion Swede outtopped all in the number of entries—120; the heaviest eighteen, from Mr. Allsop, weighing 860 lbs.

In the horticultural department of the Show some exceedingly beautiful collections of vegetables were shown; Mr. Walter, M.P. of Bearwood taking first honours. The specimens exhibited were of the highest order of excellence, not overgrown, but really good and eatable. Amongst them were Suttons' King of the Cauliflowers, with compact heads of snowy whiteness; Suttons' Improved Red Beet, an excellent kind; Suttons' Golden Globe Savoy, a beautiful-looking vegetable of a bright golden-yellow colour; and Suttons' Improved Reading Onion. The Leeks, too, were of great excellence, while Sulham Prize Pink Celery is one of the very best of the many varieties with which our seed lists are filled; and of all Turnips certainly the very prettiest is Suttons' Snowball. The second prize was won by Major Thoyte, and comprised many good specimens. The principal prize for Potatoes was also won by Mr. Walter. The Messrs. Sutton themselves exhibited—of course not for competition—a very complete collection of Potatoes, including some tubers of a new seedling Kidney not yet named, which promises to be a

great acquisition, being an abundant bearer and of excellent quality.

This, the twenty-sixth show of the series, has far exceeded both in quality and quantity all its predecessors.—*La Roi CAROTTE.*

### STRAWBERRY CULTURE.

PROFESSIONAL gardeners are familiar with the course of treatment; I shall, therefore, address myself to the amateur.

In taking runners select the second runner; it makes by far the best fruiting crown. Prepare as many 2-inch pots as there are plants required, placing a small potsherd over the hole. Sink them into the bed under the runners that have been selected. Fill the pots with the soil taken from the hole where they are to be sunk; press firmly the soil in the pot. Secure every plant either by a pebble, or, what is better, a short hooked peg made from an old birch broom. Keep the soil very moist, and do not detach the runners from the parent plants until they have well filled the pots with roots.

Want of space is one of the reasons why the Strawberry bed is not renewed at its proper season, the first week in July being a good time to make a new plantation. If planted then the plants will make good crowns before the bad weather sets in; but in July the small garden is well stocked with other productions, so that the Strawberry is neglected till such time that there is space. This neglect can be avoided by the following plan: When a new plantation is required prepare ground the size of the required bed by deep trenching and well manuring. If the soil is light well-decayed cow manure is by far the best to use, and plenty of this should be placed in the bottom of the trench, and some gradually worked through to within 2 inches of the surface. The bed should be in the most open part of the garden. It should be prepared in February, and in the following March sown with Onions in drills, and in July the Onions should be bent inwards, row to row, to admit of the Strawberries being planted in rows between them. For a small garden 20 inches asunder and 15 inches from plant to plant are good distances.

By this plan there can be a crop of Onions and a good plantation of Strawberries. No bed should continue longer than four years if in heavy soil; or if in light soil, than three years.

If there is space I should form beds for succession of the following:—

*For Early Use.*—1, Black Prince; 2, Keen's Seedling; 3, President; 4, Sir Charles Napier.

*For Succession.*—5, Dr. Hogg; 6, Sir J. Paxton; 7, Comte de Paris; 8, Eleanor.

*For Late Use.*—9, Sir Harry; 10, Frogmore Late Pine; 11, Cockscumb; 12, Red and White Alpine.

The soil will only require to be stirred deeply once during the continuance of the plantation, and then do not use the spade; a mere hoeing is all that is required to keep the weeds under. If the ground is stirred at all it should be immediately after the crop has been perfected. The plants should be mulched in November, and gently forked-up again in February. In March put some clean straw between the rows, and also between the plants, to keep the fruit from being soiled. Barley straw is the best.—*J. H., Gardener to Lady G. Legge.*

### THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 6.

LONDON when it first began to extend beyond the city limits pushed northwards. Like the stem of a plant, it grew in an upward direction chiefly; not for a good while did it strike its roots southwards, and send off to the east and west those gigantic runners we now see, the one so remarkable for splendour, the other for squalidity. For convenience sake the citizens cultivated ground lying towards the north for the supply of fruit and vegetables to the metropolis, and thus it is that we have scarcely a record until after the revolution of any nurseries situate in those districts, where they sprung-up so numerously during the Georgian era. Queen Elizabeth's proclamation, published July 7th, 1580, forbidding the continuance of the building of houses within certain limits specified, shows how London had enlarged itself then; and I dare say the poet Daniel, who had a garden-house in Old Street, near the Charterhouse just referred to, felt some satisfaction in a measure which might prevent his being interfered with by any meddling builder. As a part of the land he held bore in Elizabeth's reign the title of "The Rose Ground," Daniel may have been one of the pioneers in the course of Rose cultivation. It would be something to his credit if he could be

proved to have been a good gardener, since he was assuredly quite "small potatoes" as a poet. Old Street was originally Eld Street, possibly called after an individual. The nursery continued to be famous for many years, Oldys even going so far as to assert that it yielded not the choicest fruits in London, but the choicest in all England. That was in the reign of James I., the occupant at that time being a John Milton. In Old Street Road was the well or spring of St. Agnes-le-Clerc, deriving its name from the clearness and briskness of the water; and between St. Agnes-le-Clerc and Hoxton was an enclosed garden belonging to Charles Stuart, King of England, and sold with other Crown lands by the Commonwealth. All around it were open fields, and seemingly for pasture. And here it may be as well to make a statement which may serve to prevent a ludicrous misapprehension. The "nursery" in Moorfields was not a nursery for plants, but a training school for embryo actors, originated in the reign of Charles II. by contrivance of Von Killegrew, and here common plays were acted. Singularly enough there was a similar one in Hatton Garden, managed by Davenant. In neither case did the experiment turn out satisfactorily.

Pentonville is contiguous to Clerkenwell, almost a part of it, and here some gardens and orchards are named by old writers; indeed, it was all open land until a comparatively recent date, the only historic house being the White Conduit House. Owen Row and Street occupy the site of a large field called the Hermitage Field, cultivated by one of these eccentrics to whom I have alluded, who had most probably nothing more than a shed or shanty to live in. I presume this is the same person mentioned by a more modern author as the occupier of a plot of ground in the rear of Myddleton Place. Perhaps he had to change his location through some interference with his gardening projects. Not far from this spot there also lodged for awhile Charles Lamb, whose letter to B. Barton lets us know the fact that early in this century there was a promising nursery garden at the back of Colebrooke Row, close to the New River; and the amiable Charles, though no gardener, was delighted therewith, and declares that "the Vines, Pears, Strawberries, Parsnips, Leeks, Carrots, and Cabbages would gladden the heart of old Aesculus." This is now the site of several streets between the City Road and High Street, Islington. Islington, however, though not to appearance at all unpromising for garden cultivation in its soil and position, was principally devoted to pasturage while it was rural.

There can be no doubt that an impediment in the way of the formation of market gardens in the district was the vehement opposition made by the Londoners to the enclosure of sundry fields which they considered were lawfully theirs to disport in. It was hardly to be expected that gardeners would plant and sow on land which was unfenced and liable to be shot over, or marched upon, by the train bands and volunteers. In the reign of Henry VIII. there was a riot because the inhabitants of Islington, Hoxton, and Shoreditch had enclosed the fields with hedges and ditches, also they unceremoniously turned off all intruders, young and old alike. A party of citizens went out with the cry, "Shovels and Spades!" and having torn-up the hedges they filled in the ditches! They were too numerous to receive punishment. Again, in the eighteenth century the Artillery Company in a determinate manner opposed attempts at enclosure, and on August 12th, 1784, the regiment pulled down a great portion of a fence with which Mr. Samuel Pitt had surrounded land planted as gardens—conduct, I should say, rather unreasonable. So old Islington, instead of becoming horticulturally famous, was renowned for its cheese and custards, there being large grass farms in the hands of a few proprietors. The chronicler of Islington brags about their ability in the art of haymaking, but it seems the cowkeepers did not rely upon hay only as food for their cattle; they brought to Islington from a considerable distance quantities of Turnips and Potatoes at some cost. This they must have done, I suppose, at a time when they might at least have grown for themselves such vegetables as these without risk.—C.

### EARLY WRITERS ON ENGLISH GARDENING.

No. 2.

CHARLES COTTON.

THERE are some men who to have as friends is a guarantee that you are worthy: such a man was Isaac Walton, of whom it was well said by Ashmole, the historian and his contemporary, "He was a man well known and as well beloved of all good

men." Walton thus concluded one of his letters, "Though I be more than a hundred miles from you and in the eighty-third year of my age, yet I will forget both, and next month begin a pilgrimage to beg your pardon, for I would die in your favour, and till then will live your most affectionate father and friend." That letter was addressed to "My most honoured friend Charles Cotton, Esq." Walton calls himself Cotton's "father," in accordance with the prevailing custom with the teachers of other arts and sciences to speak of and to address their pupils as "sons." Astrologers, alchemists, and even poets adopted this term of kindness, for Ben Jonson made many such adoptions from among his friends; nor was the practice of recent origin, for in our translation of the Bible "the sons of the prophets" is the designation given to their disciples.

Cotton was born of honourable parentage on the 26th of April, 1660, at Ovingdean, close to Lewes in Sussex; but he had the worst of inheritances—the position of a gentleman with an encumbered estate and no profession. He had the best of substitutes, a liberal education. He was a member of Cambridge University, and he there became master of modern as well as of ancient languages. These were his sustainers in times of need—times too frequently recurring; so that he had to write, not of themes he preferred, but of those which suited the public taste. He complains in one of his prefaces that that taste in all things was "Frenchified," and the poetry of the period was not an exception. His poems were sufficiently impure to be praised by Sir John Suckling. Others of his popular works are irreproachable, and one of them, a translation of Montaigne's *Essays*, is still unsurpassed; but it is by his second part of "The Complete Angler" that he will be ever most remembered.

As a member of society he was justly highly esteemed. He was twice married, and by more than one contemporary he has been praised for his cheerful hospitality, his superior conversational power, and moral rectitude. Although obliged to be much in society, yet the quiet amusement of angling and the cultivation of his garden were his favourite occupations, and we are assured that he wrote from his heart's dictate these lines:—

"Dear Solitude, the soul's best friend,  
That man acquainted with himself does make,  
And all his Maker's wonders to intend:  
With thee I here converse at will,  
And would be glad to do so still,  
For it is thou alone that keep'st the soul awake."

In the State Papers there are several documents relative to Charles Cotton, chiefly concerning duels; but one shows that in 1667 a captain's commission in a foot regiment was given to him, and hence the armour he wore as represented in the portrait. He served in Ireland, and here probably met with his second wife, the Dowager Countess of Ardglass, and her jointure, £1500 a-year, was secured from his creditors. His house at Beristord, on the banks of the Dove in Derbyshire, was the frequent resort of Isaac Walton for the sake of its trout-fishing. There he built a fishing house still remaining. He entitled it "*Piscatoribus sacrum*," and had inscribed Walton's and his own initials in united cyphers over the door. His Derbyshire residence furnished him with authentic information for composing the only one of the publications which need notice before proceeding to that which entitles him to a

place in these sketches. It is entitled "The Wonders of the Peaks." In it he descants on the beauties of Chatsworth.

"This palace, with wild prospects girded round,  
Placed in the middle of a falling ground;  
On the south side the stately gardens lie,  
Where the scorn'd Peaks rivals proud Italy."

The description, however, is very meagre, and the real details then were not even approaching to the present excellences. The poet speaks in wonder of a fountain that spouted water "90 foot high," where now is that "Emperor" fountain which ejects the water to a height of 240 feet, which is 38 feet higher than the London monument on Fish Street Hill.

Being fond of gardening, and as the taste for it was rapidly increasing, it was to be expected that he would write upon its practice—the booksellers would readily purchase his production, and consequently in 1675 appeared his "*Planter's Manual*."

We need only refer to Sir Henry Wotton's writings for evidence that gardening in all its branches, and among all classes, was being pursued ardently, and that it was practised judiciously we learn from the contemporary writings of Evelyn, Rea, Worlidge, Cooke, Meager, and others.

The full title of Cotton's volume is "*The Planter's Manual*, being instructions for the raising, planting, and cultivating all sorts of fruit trees, whether stone fruits or pepin fruits, with their natures and seasons. Very useful for such as are curious in planting and grafting. By Charles Cotton, Esq." 1675. It is a small duodecimo of 139 pages, but throughout is evidently founded on practice. In the preface he warns his readers that superior fruits, especially in the northern parts, require a brick wall. He defines as he writes the terms employed:—"Espallier, a hedgerow of fruit trees against a latticed pale or stakes. Contrespallier, a hedge of fruit trees against a wall in the open air." The *Pomme de Paradis*, he states, was "a sweet Apple that comes of a Pearmain grafted upon a Quince." His enumeration of the requirements for success are a good soil, quincunx order of planting, not planting deep, not to prune at the time of planting, not to hoe deep but to break the crust frequently

in the summer, to plant in October. He gives good directions for pruning and training; but instead of nailing preferred sheepshanks fixed in the wall in quincunx order, 5 inches apart and projecting an inch, to which to tie the shoots. His directions for grafting and inoculating are unobjectionable, and he concludes with lists of fruits, all French. Among Plums he names "*L'ale vert*," is this our Green Gage?

Cotton seems to have died as he had lived, in pecuniary difficulties, for administration to his effects was granted on the 12th of September, 1687, "to Elizabeth Bludworth, his principal creditrix." In that grant he is described as living in the parish of St. James's, Westminster. Relying on that record I proceeded to the church of St. James's, Piccadilly, in the hope of finding there some memorial. Let those who have not seen the interior of this, Sir Christopher Wren's masterpiece, do so. The object he had in view was to enable two thousand people to hear distinctly and see the clergyman; he effected that object, and I think he was justified in saying, "It is beautiful, convenient, and of the cheapest form." But I was not less struck with the number of celebrated men who are there entombed, and whose memorial tablets are on the walls and pillars. The two Vandereldes, Dahl, and Huysman,

*Charles Cotton.*

Fig. 39.

painters; Arbuthnot, the friend of Pope, Akenside, author of the "Pleasures of Imagination," and the celebrated Sydenham, physicians; Gilray the caricaturist; and Dodaleys, the eminent booksellers, are only a few of those I noted. But there is no marble monument to the memory of the friend of Isaac Walton, so I obtained access to the parish register of burials, and there found this entry, "1686, February 16, Charles Cotton, M."—that is, a married man; and as the year then commenced in March, we should now record the burial as being in 1687.

### JULES D'AIROLLES PEAR.

I AM obliged by your information respecting the identity of Jules d'Airolles with Liron d'Airolles, of which I now send you a section of a rather small fruit selected as exhibiting better than a larger specimen the type of the kind. The fruit is large, with a smooth skin, bright green marked with bright red on the sun side, the bright green changing to greenish yellow as it ripens, the bright red being retained and height-

Fig. 100.

ened as the ground colour changes. Eye partially open, rather deeply depressed. Stalk about three-quarters of an inch long, rather stout, inserted in a rather deep cavity. Flesh white, delicate, melting, very juicy, with a rich vinous flavour and slight aroma. The tree appears hardy, vigorous, and a good bearer. I have it against an east wall, upright-trained, and on the Pear stock. The first fruits this year (1875) were ripe October 29th, and the last fruit used—it being over-ripe—November 18th. It is equal to—I think surpasses—Napoleon, which it much resembles.

Have any of your correspondents noticed the difference in the size and quality of Pears on the Pear stock over those on the Quince in a high cold situation? The difference is with me marked, and becomes more so every year; those on the Quince, especially Louise Bonne of Jersey, Bergamotte Espreux, Beurré d'Arenberg, Alexandre Bivort, Beurré d'Anjou, and Zéphirin Grégoire, though masses of fertility, have the fruit so much spotted and cracked as to be worthless, whilst the same kinds on the Pear stock exhibit none of those defects. The cracking and spotting have been attributed to cold cutting winds whilst the fruit was young; but I am inclined to think that whilst those on the Pear stock have not the crack-and-spot tendency, that the Quince being a more tender subject than the Pear (a native), the latter is not checked in its growth so readily as the Quince in a cold dull period, and the fruit does not become skin-bound as a staying of the feeding fluid would cause, with consequent splitting when a return to mild weather causes the flow of sap to be

free. The Quince is a native of South Europe, and must reach its limit of hardiness, and with that its usefulness as a stock in northern latitudes. I know Pears on the Quince stock attain in some places in Scotland great excellence, but some parts of the classic land are more favourable for fruit culture than many high, bleak, exposed situations in England.—G. ABBEY.

### NOTES ON VILLA AND SUBURBAN GARDENING.

THE little forcing house, whether for Vines alone or for forcing plants into flower as well, ought now to command attention. In many, if not most, suburban gardens there are many tender plants, such as Ferns, Coleuses, Begonias, &c., which have been grown during the summer in the greenhouse, and which, for their usefulness to be prolonged, require a moderate degree of heat, and in the absence of a separate plant stove it is necessary to make use of a vinery in which many plants can be grown, and generally a fair crop of Grapes also.

In the first place, the Vines must be pruned at once and cleansed of all loose bark, but no more than will part easily from the rods. Dress the Vines over with a composition of 8 ozs. of powdered sulphur, 2 ozs. of Gishurst compound dissolved in warm water, adding one quart of juice from tobacco paper, to be mixed with clay and soot sufficient to make it of the thickness of paint. Apply it carefully with a small brush, taking care to reach the bottom of every crevice, and thoroughly cover all the wood and especially round the spurs where the insects mostly secrete themselves. When the Vines are dry suspend them to the wires about half the way up the roof, letting the upper part of the Vines hang down; this assists them to break more evenly—that is, the uppermost buds will not be so much in advance of the lower buds, which will then become stronger. The house itself must be well cleaned by limewashing all brick-work, and washing, if not painting, the woodwork.

If there is a bed or pit in the centre to be filled with material for bottom heat let it also be done, whether with tan or leaves, or a mixture of dung and leaves; while the heat is rising it will be well to prepare the plants which are to occupy the places. These usually consist of Azaleas, which must be tied to their proper shape and the pots cleaned. Lilacs and Ghent Azaleas should be potted, if not already done, and those already done will no doubt need top-dressing with a similar mixture to that in which they were potted, but not unless the pots are full of roots; such plants rarely need potting every year they are forced. Then there are the Deutzias, gracilis and flore-pleno, which require similar treatment. Next come different sorts of Roses, which ought to be one-year-potted plants to do well; the same may be said of Weigela roses, Forsythia viridissima, and Dielytra spectabilis, which are all excellent forcing plants. Rhododendrons, too, must not be omitted, nor Camellias for advancement. None of the above plants need hard forcing—in fact it is injurious to them, for the colour will be pale and the growth much weakened, and the supply of flowers shortened. Then there are different kinds of Dutch bulbs; those that were first potted must be first taken, using the common single Hyacinths and Tulips first. A few of the forwardest Cinerarias should be introduced, as well as a few pots of Lily of the Valley and Solomon's Seal, but do not introduce Heaths and Epacris into such a place. The above are all common plants such as an amateur need not be afraid to grow, and which, if the following conditions are attended to, may generally be expected to do well.

Plunge the deciduous plants named above into the pit when the bottom heat has subsided down to about 65°, or not more than 70°, and let the top heat be very mild, say not more than 50° at first; this will suit both the Vines and plants and will assist the roots to make progress in advance of the shoots—a point always to be studied in successful forcing, because then the growth is stronger, and consequently the flowers are larger and more plentiful. The deciduous plants will need but little water until there is some growth upon the bare shoots, increasing the quantity as growth proceeds; but Rhododendrons and other plants with foliage must have a regular supply. Atmospheric moisture must be also provided; if dung and leaves are used for bottom heat there will be nearly moisture sufficient for a week or two on account of steam being given off; but if dry heating is used, a syringing overhead once or twice a-day according to the weather will be necessary.

Airing is another important matter. If I say that the heat not to exceed 45° or 50° by night, and be kept at 55° or not above 60° in the day with sun heat, air must be given to keep it at that, excepting in the afternoon, when if the house is closed early, say by two or three o'clock, it does not matter if the heat increases to 70°, which will be beneficial to the plants.

There must be no neglect in watching for the green fly, for the genial atmosphere produced favours their growth and increase, and on the young shoots especially they soon do irreparable injury. If the house instead of having bottom heat has only a stage on which to stand the pots, there must be greater care

still not to increase the heat too much at first, and when syringing is going on the pots should be moistened as well as the plants. Again, under such circumstances special attention is needed as to watering, because a plant not plunged but merely suspended, as it were, on a stage with both air and heat circulating freely about it, the ball of soil naturally becomes dry much sooner, and will need water oftener and in larger quantities than if the pot is not exposed to the air.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

WEATHER permitting we shall proceed with the work of pruning and nailing the wall trees. The greater part of such work is done during the summer months, but when the young growths are covered with leaves they are not so easily laid in straight, and it is also difficult to resist the temptation of laying in more young wood than is actually required. In either case we begin to go over the trees and complete the work when they are at rest. These are either "cordons" or what gardeners call fan-trained trees. Pear and Apple trees are usually trained on the cordon system; for what in ordinary parlance is termed horizontal training is cordon training after all.

Amateurs usually make the greatest mistakes in training their wall trees, the art of training such trees not being understood by those who have not been brought up to gardening as a profession; they do not lay the branches in straight, and they lay them in too thickly, nor do they feel inclined to spur-back the foreright growths so closely as they ought, and the trees become furnished with useless spurs, which make them unsightly. There is also considerable difference in the soil for furnishing the trees with fruitful or unfruitful wood. In clayey soils the tendency of the trees is to become furnished with fruitful spurs to such an extent that the trees become weak and exhausted from the want of counteracting leaf-growth. In soils of the opposite class leaf-growth is too freely produced until the trees become old; but if the knife is too freely used on the branches without a corresponding check being given to the roots a thicket of young growths will be produced and little or no fruit. A case just occurs to me as an example of what I mean; it is a Jargonelle Pear tree, perhaps nine or ten years old, in an amateur's garden. Through injudicious training and pruning it has not even blossomed, but it is now by summer pruning alone furnished with fruit buds which will in due time gladden their owner's heart.

The easiest method of training for the inexperienced is the cordon; if there is any difficulty it is in the formation of the groundwork of the trees. Shoots will not always start from the right place, but it is always possible to train the growths where they ought to be, and the leading central growth must be cut back until this is done; the side branches must be trained opposite each other, and if the wall is of brick, three courses should be between each two branches; they will be about 9 inches apart. All the treatment required is to train the branches horizontally, and stop all side growths in summer and cut-back closely now. In fan training the side branches are nailed-in from the main growths, from which they are trained at right angles. Plum, Cherry, Apricot, and Peach trees are trained on this system; and the aim of the trainer is to preserve as much bearing wood as possible, cutting away all worn-out branches or any that show traces of disease.

Apriots are much subject to gumming; if a branch shows signs of this disease it ought to be cut away and others be trained in its place, else it will die in the ensuing summer, causing an ugly blank. Peach trees should be left until the last, and as they are much subject to the attacks of red spider and aphids, it is better to unnaill all the branches from the wall and to use new nailing material; it is also a good plan to wash all the wood with strong soapy water.

### FRUIT AND FORCING HOUSES.

**Vineries.**—It is a very usual and commendable practice to grow pot Vines for the earliest crop, and forcing may be commenced at any time. The Vines may either be bought from the nurserymen who grow canes especially for forcing purposes, or they may be grown at home. It will depend upon circumstances whether it will be best to purchase or to grow them. It also depends much upon how they are started whether there will be a good show for fruit or a comparative failure be the result. They must be started in a low temperature to begin with—say 45° at night, and the roots ought to be warmer than the tops, not that a high bottom temperature is necessary or even desirable. 65° would be the best to start with; this would gradually bring on the roots until the night temperature of the house was 65°, when the bottom heat might be 86°. This ought to be the highest minimum temperature throughout, except that it may be 70° in the house when the Vines are in flower. The best sorts for forcing in pots are Black Hamburgh and Foster's White Seedling. Buckland Sweetwater is a distinct Grape, and when it succeeds is even more esteemed than the other white sort.

The weather this year has been exceedingly unfavourable for late-keeping Grapes, and the large bunches which are now so much sought after are not adapted for very late purposes. The bunches of Lady Downe's are generally small and seldom shouldered, which is one reason why they keep well when large compact bunches of Gros Guillaume are unsightly from their tendency to decay in the centre. Gros Colman is an excellent-keeping sort, and is gradually obtaining popularity for late houses. Compared with Lady Downe's it is said to keep quite as well, and for appearance far excels it; its flavour is also esteemed by many palates. It is necessary to urge again the importance of carefully cutting out with a pair of Grape scissors all decaying berries as soon as a spot of decay is perceived. We are also very careful not to sweep the passages or any stages that may be in the house so as to cause dust.

### GREENHOUSE AND CONSERVATORY.

Here it is also very necessary to guard against damp, as, with Grapes, large close soft-petalled flowers suffer most, but the removal of decay is the best way to preserve the flowers for a length of time. Cyclamens require much attention in this respect; scores of flower buds cluster at the base of the leaves, and not only do these buds become mouldy, but the stalks of the leaves decay and the leaf falls down amongst the buds, causing much damage in a day or two. We brush the leaves aside with the hand and pick all the decaying parts out as often as it becomes necessary. When water is applied to the roots it is best to pour it carefully in close to the rim of the pots. Stage Pelargoniums are now placed very near the glass, and are watered but sparingly. The only insect to be feared is the green fly, and the plants will not remain healthy if this is allowed to increase. They are also subject to a disease termed "spot." The prevailing cause of this is a close atmosphere, or the plants are placed in a position where the air does not play freely amongst the leaves. Too much water at the roots is also very injurious to them. The fancy varieties are even more tender in their constitution than the other sorts. They require to be potted in lighter soil, and in other respects must have more attention, not only now but all through the growing period.

Cinerarias are coming in very useful at this time. There is great variety and brilliancy in the flowers, white, rose, crimson, and red shades, and from pale slaty blue to intense deep blue, others having flowers of the richest plum purple, and the flowers are so lasting in their character that a continuance may be had from now until April. A variety of flowers are obtained by forcing, and when a large supply is required a forcing house is essential; but it is always possible to introduce a few Roses, Hyacinths, early Tulips, *Dialytra spectabilis*, and spring-flowering shrubs into theinery; when a bed is made up it is an excellent opportunity to obtain the requisite amount of bottom heat, and the temperature required for the Vines is that most suitable for the plants.

Amaryllises are now at rest in the coolest house, no water at all being given to the roots until they are introduced to heat. It may also be noted that they do very well in the earlyinery. The gentle bottom heat promotes root action, and as soon as the flower buds and leaves begin to grow out of the bulb, the pots, if necessary, may be removed to a house with a higher temperature. We usually place them on a shelf near the glass in the Pine house, where they enjoy a temperature of from 60° to 65°. Amaryllises are sometimes grown in over-large pots. No error in culture is greater than this. The largest pots that we use are 8-inch, and many of the bulbs are potted in a size smaller. Stiffish loam, with an admixture of sharp silver sand and a small portion of leaf mould, is the best potting material. We drain the pots well. A succession of flowers is obtained by introducing a few pots at different times.

### FLOWER GARDEN.

All the beds usually devoted to summer bedding plants, and those that are not planted with spring flowers, may be dug or trenched at a time that is most convenient, but the treatment will be different according to the nature of the soil and also of the annual rainfall. Even in what is usually considered wet seasons our plants suffer from drought, and water is not easily obtained. The plan is to trench the ground and manure it highly with cow-dung principally, placing a layer at the bottom of the trench, and this is done about every alternate season, and it is seldom that water is required. Should a very dry period occur, a good supply of water is given and the ground is mulched with short manure. On heavy soils and where the rainfall is much more than ours, treating the beds in this way would only cause a very luxuriant growth of leaves with few flowers.

We look over the Auricula frames about twice a week and remove all decaying leaves, watering such plants as require it. After this time water will be almost withheld for two months or more. Carnations and Picotees are also looked over in the same way.—J. DOVELAS.

### TRADE CATALOGUES RECEIVED.

Robertson & Galloway, 157, Ingram Street, Glasgow, and the Nurseries, Helensburgh.—Catalogue of Roses.

Edwin Cooling, Mile-ash Nurseries, Derby.—*Catalogue of Roses, Fruit Trees, Ornamental Shrubs, and Winter-flowering Plants.*

O. Kilminster, Burgess Hill, Sussex.—*Catalogue of Dutch Flower Books.*

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix upon the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Young Hopeful*).—As you need a cheap work, our "Garden Manual" will suit you, free by post for twenty postage stamps. (E. Y.).—You do not say whether you wish for a book on gardening, or for general instruction, or for mere amusement.

GRAPES AT OSMESTON MANOR.—We have one or two letters confirming the explanations we gave. There was no imputation that Mr. Harrison is not a skilful gardener, and therefore we need not occupy more space relative to the subject.

ADVERTISEMENT FOR GARDENERS (F. H. F.).—Every gentleman advertises for the kind of assistance he requires, and no one need be offended. Many men who are not qualified for a head gardenership would very efficiently manage a small garden and help in other ways.

SHEARS (E. W.).—We are obliged by your sketch. They are a good variety of garden shears, and are well known.

LIGUSTRUM JAPONICUM (C. R.).—This beautiful evergreen shrub, of spreading bushy growth, with large white flowers "like a white Lilac," is perfectly hardy, but is improved by a sheltered position.

PROPAGATING LEUCOPHYTON AND ALTERNANTHERA (C. A.).—*Leucophyton* Browni is hardy in light well-drained soil, but in wet heavy soil is liable to go off in winter. Plants may be taken up, potted in light soil, and wintered in a cold frame with protection in severe weather. Propagation is effected by division in spring, or the wiry "spray" may be put in as cuttings in gentle heat. *Alternanthera* should be potted or placed in pans, and wintered in a temperature of 50° to 55°, and encouraged in February with a brisk moist heat, the cuttings being put in March in a good bottom heat, and grown-on so as to make nice plants by planting-out time.

VINES PRODUCING SMALL GRAPES (*An Irish Subscriber*).—Give the border a dressing of rich compost—light turfy loam, with one-third of manure added, a fourth of charred vegetable refuse, and a fifth of half-inch bones, or three parts turfy loam, and one part each manure, short and fresh, charred refuse, and half-inch bones, the whole being well mixed. Remove the surface soil to the depth of 8 to 9 inches, if you can go so deep as the latter without injuring the roots, and replace with the fresh compost one-third thicker than the soil removed. This may be done now, mulching over the surface with littery manure, removing the littery part in April. A sprinkling of guano over the surface of the border washed-in with water at a temperature of 75° when the Grapes are set, and again when the first indications of colouring appear, in each case making the surface of the border quite yellow with the guano or 4 lbs. per square yard, will be of great benefit to the Vines.

TREES FOR CEMETERY AVENUE (*A Sub. to "Our Journal"*).—If the situation be sheltered, not bleak and exposed, the Decid. (*Cedrus deodora*) would be the most suitable, and the next best in evergreens *Lawson's Cypress* (*Opuntia Lawsoniana*). If you want shade for the footpaths you could not have anything better than Limes, the red-twigged variety being best, *Huntingdon* Elms being good, also common and purple Beech.

PRUNING CLEMATIS (G. Killarney).—The plants having become bare at bottom, your only plan will be to cut them down to within a foot of the base, and depend upon shoots being emitted from latent buds at the bottom of the stem; but if the stem be devoid of them your best plan would be to disentangle some of the shoots and train them downwards over the trellis and as low as you can, depending upon the shoots they give next year for covering the trellis equally throughout, which can only be secured by frequent regulation of the shoots during growth. Propagation may be by layers made now of firm shoots. Prune the Clematis in early spring before growth takes place. *Deutzias* and *Syringas* require no pruning beyond shortening irregular growths and cutting out old bare wood. Do it in winter after the leaves have fallen, but in mild weather.

PROPAGATING RHODODENDRONS (*Idem*).—Grafting is practised for the choicer varieties, the stock being potted the winter previously, and kept plunged in coal ashes in a sheltered situation over the rim, and duly seen to for water in summer. Grafting is best done at the close of August or early in September, side grafting being the most eligible mode, the plants after grafting being shut up in a frame, the lights inside brushed over with whitening brought to the consistency of whitewash with skim milk. Cuttings of the young wood inserted at the same time in sandy peat, surfaced with an inch of silver sand under a hand-light or cold frame, shaded and kept moist, and if given a gentle bottom heat after a callus is formed they will root more surely and speedily.

DIVIDING GLADIOLUS (*Idem*).—Take up the clumps the early part of next month, whether they have foliage or not, and planting again the same day, they will sustain no injury.

TEMPERATURE FOR *TODIA SUPERBA* AND *ADIANTUM FARLEYENSE* (J. P. Jun.).—The *Todia* will do in a cold house, but better in a house from which frost is excluded, to which we should at once remove the plant. *Adiantum farleyense* requires a stove, or in winter a night temperature of 60° to 65°, and day 60° to 65°. *A. acuminata* and *A. cuneatum* will succeed in a house from which frost is excluded; but *A. cuneatum* grows better in a cool stove or warm greenhouse.

GRAFTING VINES (E. K.).—The stocks should be cut-back at once to where you propose to graft, and the operation should be performed when the house is started, putting-in the grafts by the usual tongue or whip-grafting, and on the upper side of the rods. The stocks cut-back now should be pared smooth, and have applied to the cut part Thomson's styptic or patent knotting used by painters. This will leave no wound for bleeding only where the scion is inserted, and this should be well secured. Have two eyes to the scions, using grafting wax in preference to clay, covering over the junction with a little moss, sprinkling with water three times a day lightly.

GRAFTING CAMELLIAS (*Idem*).—Whip-grafting is best, as by it the neatest and best junction is secured, and the best time for performing it is in spring, just when the plants are commencing making fresh growth; but it must be done before the scions have commenced to push, the scions being of the well-ripened growths of last year, and with three or four leaves or joints. After grafting place the plants under a handlight in a house with a temperature of 55°; and if the pots are plunged in a bottom heat of 70° to 75°, they will unite more speedily and with greater certainty. In six weeks the union will be complete, the bandage should be loosened, and the plants gradually hardened-off, but continued in heat until the growth is complete, then removed to a cooler house.

PARSNIPS CANKERED (B.).—The cankered surface is due to the attack in the early stages of growth of the Carrot-fly (*Pila rosea*), or *Pila nigrescens*, and we have known canker result from the boring into the roots by the maggots of the Crane-fly (*Tipula alaracea*). Quicklime and soot pointed into the ground at sowing time, half a bushel to each per 80 square yards, is a good preventive, but a better remedy is gas lime at the rate of half a peck per rod (804 square yards), or twenty bushels per acre. The ammoniacal liquor of the gasworks diluted with six times its volume of water, and applied to the ground with a rose watering-pot a day previous to sowing, is also a good preventive of canker. After an attack of maggot the plants go very much to top, having remarkably fine luxuriant foliage.

REMOVING ROSES (H. B.).—Leave them as they are until required to be moved, keeping the growths after July shortened rather closely, preventing as much as possible long sappy growths from being made. In removing keep the roots from drying winds, and by watering at planting, and sprinkling overhead daily if the weather be dry, you may safely move them in September.

PLANTING ORCHARD (*Gregory Young*).—The trees are sufficiently close together without the Plums between each line of Apple and Pear trees, which will only leave the trees 18 feet 6 inches apart, whereas they should not be less than 30 feet, better 34 feet apart. We should remove the Plum trees, or increase the distance to 34 feet, or you may leave the Apples and Pears as they are and plant the Plums elsewhere 24 feet apart. This distance is not too much, especially as you propose growing bush fruit in addition to the standard trees. We should trench the ground at least 18 inches deep, and loosen the bottom of each trench another 6 inches, but not bringing to the surface more than 6 or 8 inches of the previously unmoved soil, and apply the manure to the surface, and pointing it in. It would be desirable to give some well-rotted manure well mixed with the soil used for planting with.

SOIL FOR ROSES (S. M.).—Your black loamy soil, with the addition of a fourth each of the marly clay and old hotbed manure well intermixed, will grow the Roses well, the ground being trenched 2 feet deep, and the manure added and mixed with the soil as the work proceeds.

PREPARING GROUND FOR DAMIELIAS (*Idem*).—We should have the soil trenched now two spits deep, placing between the top and bottom spit a liberal dressing of manure, and place the marly clay on the surface after trenching, and throw up the soil as roughly as possible for the winter. During the first dry frosty weather after the middle of February fork-in the marl, throwing the ground level, and in March apply to the surface a liberal dressing of well-rotted manure, and fork it in during dry weather, again turning the surface with a fork at planting time.

PRUNING ROSES (T. Kenneth).—Having planted them this month we should not prune them until February, and the dwarfs at the same time, in both cases pruning rather closely—i.e., the strong shoots to three or four eyes, the medium to two, and weak shoots to one eye of their base. Secure the plants against winds, and if frost prevails in February defer the pruning until milder weather.

PEAS FOR A SMALL GARDEN (*Idem*).—William I. (Laxton's) is the finest of all early kinds, attaining to a height of about 8 feet. It may be sown at the beginning of next month in a warm situation, or the first open weather after the middle of February or in March, sowing at the same time Best of All (Maselem's), which attains a height of about 8 feet, and the latter-named kind at intervals of three weeks up to the middle of June, putting-in at the same time Omega (Laxton's) about 24 feet, and these will give you a supply of Peas of the first excellence up to October, and later if frost permit.

SELECT CARNATIONS AND PICOETTES (*Idem*).—We name a dozen of each, the first-named in each class being the most moderate in price. *Carnations*—*Crimson Biscarres*: Eccentric Jack and Isaac Wilkinson. *Scarlet Biscarres*: William Pitt and Campanini. *Purple Biscarres*: Purify and James Taylor. *Purple Flakes*: True Blue and Ajax. *Scarlet Flakes*: John Bailey and Superb. *Rose Flakes*: Mrs. Martin and Sybil. *Picoettes*—*Red-edged*: Mrs. Keynes, Princess of Wales, and J. B. Bryant. *Purple-edged*: Mary, Alliance, and Mrs. Little. *Rose and Scarlet-edged*: Gipsy Bride, Juliana, Mrs. Allcroft, and Mrs. Fisher. *Yellow Grounds*: Prince of Orange and Claude. If you only want them for cut flowers the Clove Carnations are good, and there are now some very fine varieties, as King of Yellows, Bride, Prince Arthur, Grand des Batailles, Maiden's Blush, and Christine; and of *Picoettes* Mrs. Kalk, Sparkler, Amazon, Margaret, Gem of Roses, and Beauty.

RENOVATING VINERY (R. A. W.).—The border inside ought to be the full width of the house, especially if you have no outside border; but the present width of outside border we should retain in addition to the inside border, having the front wall with 2-foot openings and 14 or 18-inch pillars, the openings the depth of the border, and arched over, or a stone head placed across the openings and only a few inches below the level of the border. The openings and outside border may be made after the Vines have been planted a year or two. To have Grapes in June you will require four rows of 4-inch pipes along the front of the house. We do not recommend any particular kind of boiler, but we advise you to have one sufficiently powerful to do its work with ease. You may plant the Vines inside and still continue the present Vines, but we should not continue them more than a year; and if the Vines are closely planted, or if they cover the roof, it would be well to discard the old Vines at once, for the young Vines must have room for their foliage to be fully exposed to light and air, so as to secure the thorough ripening of the wood. Plant strong or fruiting canes, but do not allow them

to fruit the first season. All the Vines named, except Black Hamburg, are unsuitable for ripening in June, but are good for a late house to be ripe in August and hang until after Christmas, and some will hang in good condition until March. Black Hamburg, Duke of Buccleuch, Mill Hill Hamburg, and Foster's Seedling, or Buckland Sweetwater, would be suitable for the earliest house.

**TODNA SUPERBA (D. W. H.).**—It should be wintered in a cool house, but frost should be excluded, as, though a few degrees of frost may be endured by the plant, we have known the fronds discoloured thereby. It requires a compost of rough fibrous peat, with some crocks (broken pots) intermixed about a sixth, and good drainage, affording moderate pot-room.

**RENEWING VINE BORDER (Idem).**—With an inside border you may renew the outside border, and that without losing a crop of Grapes. It is not necessary to place charcoal next the roots, but mix it with the soil. The lifting of the Vines and renewing of the border would be best done just before starting the Vines, giving a covering to the border of hot dung and leaves ten days or a fortnight before applying fire heat. The lime rubbish should be removed and mixed with the compost of the border, but one-third of it will be sufficient for that purpose, and in place of the lime rubbish have that more depth of properly prepared border, 15-inch depth of border being much too shallow.

**ORDERING CAMELLIAS, &c., FROM GHENT (B.).**—Orders for these are best given in early autumn, so that the plants may not suffer in consignment from severe weather, as they are liable to do if transmitted during the winter months.

**CHRYSAETHUM JULIE LAGRANIERE (J. F. F.).**—It is not a Pompon, neither is it a large-flowering variety. The blooms are medium-sized, reflexed, of a reddish crimson colour, and are produced in great profusion. The plant is a sturdy grower, and is seldom affected with mildew. It is one of the most useful varieties that can be grown for decorative purposes and for affording a supply of cut flowers.

**CHRYSAETHUMS (J. W. A.).**—They are florists' flowers, of which we cannot name the varieties.

**DIONA MUSCIPULA (H. T.).**—It very rarely ripens its seeds in this country, therefore is usually propagated by dividing a plant.

**NAMES OF FRUITS (W. D. P.).**—Boston Russet. (Kestford).—A, not known; B, Comte de Laury; C, Napoleon; D, Marie Louise. (J. M. J.).—1, Pearson's Plate; 2, Franklin's Golden Pippin; 3, Oransea; 4, not known; 5, Jean de Witte; 6, Grand Soleil. (An Old Subscriber).—1, Ostillo; 2, Deux Sœurs; 3, quite rotten and shapeless; 4, not known; 5, Kerry Pippin; 6, Powell's Russet. (G. Head).—1, not known, worthless; 2, Colmar d'Arenberg; 4, Black Worcester; 5, Braddick's Nonpareil; 7, Pitmanston Russet. (W. H. Ashurst).—1, English Codlin; 2, Uvedale's St. Germain; 4, Braddick's Nonpareil; 5, Hanwell Bouring; 6, Loen's Pearmain. (Easton Newton).—1 and 2, Beurre Diel; 3, Pitmanston Duchess; 4, Vicar of Winkfield; 5, Van Mons Léon Leclerc; 6, Glou Morcean.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### POULTRY FARMING.

At the request of many inquirers I promised to give publicity to my opinion of the best and most profitable plan of keeping poultry of all sorts.

I have always urged that grass runs are absolutely necessary; but I believe most will agree with me that the greater number of their fowls will not seek over a large space of ground, and to rent for the purpose of poultry-breeding a number of acres specially is an extravagance.

In 1873 I devoted a large field of 14 acres of turf from Christmas to Midsummer to fowls only, as I found in early spring and summer a large loss and annoyance from cattle, sheep, and horses grazing with them, on account of the coops being constantly upset, and wire partitions, &c., damaged by rubbing against them. So I determined at once to set apart a portion or portions in acre lots, and after repeated alterations I am satisfied that if those who intend to keep fowls (no matter how many), but as a guide not less than one acre per hundred should be allotted, will follow the plan now submitted (although the cost, as a start perhaps, looks large), they will find economy in the end in money, time, and trouble.

I often notice correspondents are advised to devote too much hen-house room. For one hundred adult birds I consider an acre of grass is ample, and according to the determination to keep flyers or non-flyers, erect a wire fence 6 feet high in the former case, and 4 feet high in the latter, entirely round the four sides of the acre, erecting in the centre of the ground a wooden or other house 5 yards long by 4 yards wide, measuring to the eaves 4 yards in height, the roof of which should be a double span, having in the 5-yards length four stretchers of 4 by 3 to tie the roof together. Upon these bars should be three or four perches laid to suit the birds that roost high. On either side of the roof should be a skylight to lift up to give light and ventilation according to weather, hinged at top. The under side of these should be wired so as to prevent fowls making an exit by them.

The floor should be fixed 4 feet from the ground, so as to afford a space underneath the hen house proper for shelter in damp and windy weather. On all four sides of this under space should be two doors 2 feet by 2 feet, the bottom being 6 inches from the outside floor, about 3 feet from each end of house. Previous to setting joists to carry the floor some rough slates should be laid horizontally all round underneath and touching the joists to prevent rats from climbing into the top house. To form a roosting-stage fix four pieces of 4-by-2-inch timber in a

slanting direction, the foot of each being placed 6 feet from the side of the house, and the top resting against the side near the roof. These lean-to's will form rafters, and on each, at every foot from the top, place a piece of wood of the shape of an L to form sockets in which to rest the longitudinal perches. These should be of 1½ by 1½-inch timber, and they can be removed at pleasure to clear away the droppings underneath. This frame of perches forms roosts suitable for all birds, high or low roosters, and one of the particular advantages is that the fowls all roost together with the tail to the wall, as the long toes will clasp the 1½ and the short the 1½.

Wire netting should be fixed from each angle of the hen house obliquely to each angle of the acre, so as to form four separate quarter acres of ground, and the partitions must be netted sufficiently high to keep the birds in their proper compartments. The main entrance should be where it is best seen from the dwelling house, and to be used for cleaning out, gathering eggs, &c. It should be 5 feet by 2 feet 6 wide, and fixed so as to avoid opening against the roosts. Inside the upper house along the wall, starting at each end, have standing a frame, not a fixture, but secure, forming seven nests in a row 18 inches square, in three or four tiers, each nest having a piece of board running across the front 8 or 4 inches high to prevent the eggs falling, and if two 10-inch boards are used for the horizontal divisions it will afford a walk of 6 inches for the fowls to alight or tread upon when seeking a nest. The nests should be 9 feet 6 wide, and about 4 feet 6 high if three tiers of nests are used. In the centre of the upper house should be a shallow oval or round utensil as large as convenient into which the ashes—that is, the grit, &c., after the household cinders have been riddled, should be emptied, and if insufficient, dry sifted soil, to both of which should be added black sulphur, and every other day or two with a small shovel (after the birds have had time to dust and pick out useful scraps) sprinkle in rows over the droppings under the roosts, so deodorising all noxious effluvia. During the summer months this manure should be removed once a fortnight, and the roosts scraped and greased with a mixture whilst melted of lard, sulphur, and paraffin oil (1 lb. of the first to 1 oz. of each of the two latter), and every crevice or crack should be filled up. Every three months or oftener the houses should be white-washed, taking care to mix with each bucketful half a pint of carbolic acid or paraffin oil, and to be rubbed well in every crevice and joint of woodwork where vermin are sure to lodge. Carbolic acid powder should occasionally be sprinkled through a dredger in and about the house, runs, &c.

The advantages claimed are that the fowls have a constant weekly change of keep, passing over the whole acre once a month. It is preferable that each half, or some portion least in the way for walking, of each quarter acre should be dug up during its term of fallow, and in all such cases to now and again sprinkle straw over that part, and spread all the dry grain given to the fowls upon the dug portion. There is always a week to dig up such a small space of ground. Occasionally a drill or two of various grains might be introduced, so as when the fowls come on that part again they will seek for the sprouted corn. The straw will be found a great acquisition, as the birds will not too readily get their food, and will continue for hours to search for it, and when finding that they are sure at the same time to find insects, &c., besides giving healthy exercise.

When the hatching season commences the hens should be set elsewhere, and when chickens come the adult fowls can be in one space and the coops containing mother and chicks in another space, and so fed upon better and more expensive food, which is often consumed by the larger birds. Then again, when cockerels intended for killing attain a certain age and require fattening they can again for a short time be fed separately, alternately changing the coops and chicks, and closing or opening the doors of the under compartment. A small roost house made moveable could be used by the fattening birds. Again, in late autumn when early pullets are about to commence laying they require more nutritious and warmth-producing food, and this can be facilitated by this mode. I am quite satisfied where young and old run indiscriminately—not even calculating loss from being lamed and crushed, but simply the extra and more expensive food, intentionally given and required by the young, which is in such cases insatiably devoured by older birds—the cost is nearly if not more than trebled during the year, the saving of which, besides the comfort of having all under control, would quickly repay the cost of a suitable structure. I omitted to say that the ventilator over the roosts should be glazed and a piece of timber fixed hanging down from the upper portion where the hinges are fixed, so as to thoroughly light the roosts and yet break the bright glare that would otherwise shine over the nests. That on the opposite side should be fitted with a sine or non-transparent plate.

I advocate the use of milk from early in November till the end of March. I gave last winter £13 worth, also during the same months Tyler's patent amalgamated meal and Brown's aromatic compound as very first-class warmth and egg-producing incentives. Of course there are many others very good, but

more expensive for non-exhibition fowls. In all cases where soft food is given it is best scattered upon the turf in different corners each morning.

It is not necessary to keep a cock with a number of fowls. I cannot account for it, as I can see no reason why it should be, but I have seen repeated instances where birds have laid more eggs for a given number of the same breed and age without the male bird than with one. It is better to pen five hens with a cock a few weeks before the required time for hatching, and make sure of almost all the eggs being fertile. Every cock will during the year lessen the profits 10s. at least.—GALLINACULTURIST, *Hampton-in-Arden*.

### KILMARNOCK ORNITHOLOGICAL ASSOCIATION'S SHOW.

THIS was held in the Corn Exchange Hall and Butter Market on the 12th and 13th inst. The Pigeons were arranged in the large hall in rows, at a convenient height for observation. The Canaries were hung on the wall at one end. The poultry and Rabbits were shown in the Butter Market adjoining the hall, on a lower level. The Society may be said to have reached a mature age, and to be one of the oldest in the country, being established in 1863.

The poultry were a large show of 608 pens. To show the difference between Scotch and English tastes we give the numbers of pens exhibited of each variety:—

Spanish .....	12	Scotch Greys .....	27
Brahma Pootras .....	19	Bantams .....	183
Cochins .....	18	Malays .....	6
Dorkings .....	87	Other varieties .....	6
Game .....	153	Ducks, Geese, &c. ....	83
Hamburgs .....	78	Selling classes .....	61
Polands .....	13		
French .....	22		608

It will be seen from this that the China fowl is not in repute about Kilmarnock. The Scotch people being eminently a practical people have almost discarded the Brahma fowl and its relatives. There are not wanting evidences from England also, judging from letters that appear from time to time in the poultry papers, that Brahmas and Cochins are on the decline.

We were much struck with the fine display of *Game* fowls. They seem the favourite breed about Kilmarnock. The twelve pens of undubbed *Game* showed from the faulty combs of some of them, that were Nature left alone the places of the dubbed ones might often be reversed. The *Hamburgs* were also a good show. Though small fowls they are good layers and consume little food considering their size, and as ornamental fowls we consider them entitled to about the first place among poultry. *French* are increasing and already number more than Brahmas or Cochins, a position they ought to hold we were told. The class for *Scotch Greys* contained twenty-seven pens, and was one of the best in the Show. We never saw such a good lot together before. Although not to be considered ornamental poultry, they have other good points in such perfection that they are sure to increase in public estimation. Of *Bantams*, while Black-breasted Reds, Piles, and Duckwings were shown in considerable numbers, only two pens of Brown Reds put in an appearance. Sebrights were, as they always are at Kilmarnock, well to the front.

The Pigeons were a first-rate collection of 446 pens, and when we say that out of this number Antwerps were eight, Dragons only four, and common Pigeons nineteen pens, this makes 415 pens of really fancy Pigeons. The Pouters were judged by Mr. Huie of Glasgow, his announced colleague, Mr. George Ure, being prevented attending. Mr. Jones judged the rest.

Commencing with *Pouters*, 123 pens, the classification adopted was, as suggested in this Journal—viz., to class Mealy with Blue, rather than with the artificial Black Red and Yellow. The first class was for Black Red or Yellow cock, standard Pied—that is, without any glaring mismarking, for pied to a feather no one expects or can expect to see. No. 610 (Andrew Dunleavy) was a Black of fair colour, rather gay on crop, but a well-shaped bird. No. 611 (David Thomson) a Yellow of fair colour and good proportions, well-feathered limbs, good crop, wanting in pinion. To him was awarded second prize. No. 612 (James Walker), third prize, a Red of good colour, well-marked crop, and wanting in pinion. He was a stylish kind of bird, but too much cow-hocked. No. 618 (Thomas Wood, York), highly commended, also a Red of fair colour and style. No. 614 (James Walker), fourth, a very good-coloured and marked Yellow, with well-shaped and feathered limbs; an upstanding bird, a trifle short in feather. He was to our taste, considering everything, the second best in the class. No. 616 (Ridley & Dye), first and special, a glossy Black of very correct marking except a rather small bib. A very handsome bird of fine lines and finished looking. Clean limbs beautifully set and feathered. All over a good Pouter, he is a credit to his exhibitors, who carried off the cream of the Pouter prizes. Credit is also due to the breeder of all, or nearly all, their fine exhibits, Mr. Mitchell of Glasgow.

No. 617 (B. H. Blacklock) an unnoticed Red of a good stamp in colour, marking, and shape, worthy of highly commended we thought. No. 618 (Ridley & Dye) a Yellow, good colour and stylish, but too deficient in marking for a "standard Pied" class. In this class Mr. Mitchell showed his old Yellow bird, but besides being of a bad colour and no great marking, he is down from age, loose-feathered, and quite out-classed. Blue or Mealy cock, standard Pied, were twenty-one in number. The first of note, No. 623 (A. Dunleavy), highly commended. A capital Mealy of a light tint, well-out moon, but not easy to say anything about pinion from his light colour. No. 623 (James Ferguson), a Mealy of a better colour, brighter red in beak and bars, but not of the same proportions as the last. No. 624 (James Walker), fourth prize. Blue, well-marked, good in colour and style. No. 625 (Hugh Thomson), highly commended, a very good Mealy, but rough-legged and rather wide on them. No. 626 (Ridley & Dye), first and special, a Blue, such another as their Black in the previous class—an easy win. No. 628, same owners, second prize, a Mealy, large and fine, well marked, but not a good colour. We would not have placed him, he was so loose-feathered and down on the wings from age. No. 631 (J. Mitchell), third. This bird was, we were told, full brother to the first-prize one, and rather better in every respect excepting being too gay on the crop, which takes away his finish. Still we would have given him the Mealy's place. No. 634 (R. Crow), highly commended. In many respects a fine bird but with too small a moon. No. 635 (Andrew & Cunningham), a first-rate Blue, but much too white on crop. No. 637 (James Walker) was a handsome Blue and evenly marked, but looked shortish in limb. Class 41 was for Pouter cocks, any other colour, standard Pied, and included Whites. Here, again, Ridley and Dye came in first with a very fine White, long in feather and limb, slim-girthed and good in crop. Second prize fell to an immense and handsome bird, something between a Sandy and a Mealy, but more inclining to the latter, as he had faint bars. He showed a good sprinkling of black ticks about the head and body. We should think he was about the biggest bird in the Show. Both third and fourth prizes went to good Whites; in fact, except the Mealy or Sandy spoken of, the class, composed of fourteen birds, was all White except No. 655 (J. E. Spence) a Red Chequer. He is a handsome shapely bird, and though chequered with a powdery tint on his body feathers, his neck and wing secondaries are of a deep rich red, richer and darker perhaps than the colour of any other Red Pouter in the Show. The next class, 42, for Black, Red, or Yellow Pouter hens, standard Pied, brought out nine birds. The winner was easily found in No. 660 (Ridley & Dye), first and special, a sweet Black hen as near perfection as generally found. She was good in every point, especially in due proportion of limb and feather. Her limbs nicely set and feathered; colour good and marking also. As is too often the case, her moon instead of ending in fine points ran up to her eyes, and this was the only eyesore about her. No. 663 (James Walker), second prize, marked in catalogue Red, was a Yellow of fair colour but not well marked, having no pinion. No. 664, same owner, third prize, marked in catalogue Yellow, was a fine Red (they seem to have transposed these two pens), the best Red for colour in the Show, finely-out moon, but no pinion, well-shaped and feathered limbs. We would have made the Red second, and the Yellow third. No. 659, still the same owner, was a solid-winged Black of fair colour and good style. Eleven Blue and Mealy hens competed in the next class, 43. Here, again, Ridley & Dye were successful, taking both first and second prizes with Blues. Both were well-marked nice birds, but though the first was the largest the second was the nicest in shape, but was unfortunately Kite-barred. Mr. Mitchell's well-known Mealy came in third, and a most taking hen she is, one of the slim-girthed kind that never thicken. She is over three years old now, and but for the fact of her having a division of colour in her moon, otherwise finely out, dividing it into two parts, she would not have been beaten by any Pouter hen in the Show. No. 674 (J. Walker), fourth prize, a Blue finely marked and stylish, quite as good as the other winners, and taking them together they were a very even lot. No. 675 (D. Lawrie), highly commended, well marked, but wanting in general finish like the winners. The next class, for hens of any other colour, standard Pied, including Whites, brought out only eight. Here James Walker, No. 676, was first; and Ridley & Dye, No. 677, second with good Whites; third and fourth fell to Joseph Scoular and John Scoular with hens of the same colour, and all the four were of a handsome and stylish appearance. No. 679 (B. H. Blacklock), a very glossy and good Black, wrongly entered in this class. Twenty-two young Pouter cocks bred this year comprised Class 45. No. 686 (A. Hutchison), commended; a tidy little Mealy of good shape. No. 688 (J. Walker) a dull-coloured but evenly-marked handsome Red, commended. No. 689 (Thomas Wood), highly commended, a slightly-made Red cock, of colour much above the average, and heavily stained on the rump and tail as many fine Reds are. No. 690 (Hugh Thomson) Smoky Black, otherwise a good bird and well marked. No. 692 (Hugh Thomson), first and

special, Black, worthy of the honour, good colour, nicely set limbs properly feathered, and marking about perfect. No. 698 (Ridley & Dye) fourth, Black, stylish but no pinion. No. 694 (Hugh Thomson), commended, a very nice Blue, short of marking, with very good limbs. No. 708 (James Walker), third prize. A really handsome well-marked Blue of good proportions but ticked all over with slight chequer marks and brown-barred. No. 704 (James Walker), second prize, rightly placed, Blue, not a large bird, but very comely. Pouter hens of any colour, bred in 1875, were fourteen. No. 707 (David Thomson), fourth prize, Yellow. No. 712 (R. H. Blacklock), second, a Blue exceedingly handsome and well-shaped. No. 713 (Ridley & Dye), highly commended, Yellow. We preferred this one to the fourth, having better cut moon, and better set legs. She was solid-winged and not very lengthy. No. 714 (James Mitchell), first prize, a good-coloured Black, long in feather but with scarcely enough limb, and rather wide set. In marking also rather deficient having little bib. No. 718 (James Walker), third prize, a Blue, a good bird. No. 719 (J. Walker), highly commended, a fine rich-coloured Yellow. Class 47, Any other Pouter cock, seven entries; and Class 48, Any other Pouter hen, five entries, we considered decided mistakes. Whatever the body colour of a Pouter is, if he is decently marked and with good points otherwise, we can admire him, but a lot of solid-breasted, solid-winged, ring-necked, bishop-sleeved birds, some with blazes up to the crown of the head, and others white from the lower mandible to the thighs, wanting both bib and belt, are nothing but an eyesore. The meagre number of entries showing that there are either few such birds about, or that their owners are disinclined to exhibit them, should prevent the repetition of such classes. The only birds eligible for it are, in our opinion, Splashes, by which we mean Whites with coloured tails, or slightly marked about the head and back, but not to such an extent as to come under the definition of mis-marked birds, and as none of this description were visible we conclude that no class is wanted for them.

**Carriers.**—Ridley & Dye were first and third in cocks of any colour with a good Black and a good Dun. The Black was especially good in wattle, good also in general style, being long-feathered and long-necked. He did not, however, stand-up on his legs so well as the Dun. Mr. Hugh Bankhead was successful in taking second, and Mr. McCrae fourth. In hens the first went to No. 744 (Alex. Smith), a very good Black, as glossy in colour as any Black Pigeon we ever saw, and with wattle and eye both good. She was a fine upstanding and proportionate bird, and stood quite away from the others. The class for young Carriers of any colour or sex contained twenty, mostly Blacks and Duns, and many of them of great promise. Mr. James Ross was awarded first prize, and Mr. E. C. Stretch second.

Only eleven Short-faced *Tumblers* competed, mostly Almonds, and not a few of them showed they had been altered from what Nature made them. No. 777 (Bryce) was first and special with an Almond cock clearly before the others, not only good in colour but also in head, beak, eye, and carriage.

**Barb** cocks were also eleven, the winner of first and special being E. G. Keay's Black, Mr. Bryce's Dun being second, and his Black third. 785 (Spence), a good Yellow cock was very ill-looking and seemed unlikely to reach home alive. We cannot understand how Barbs are called by some so high-class as to be out of the category that includes Jacks, Owls, Fantails, &c., and to be considered equal with Pouters, Carriers, and Short-faces. We always thought that any Pigeon fit to be named beside these three breeds, must, like them, have something beyond mere fine points—viz., a certain highly-bred way of carrying themselves, called shape or carriage. We never saw anything of this in Barbs, and without it they never can be allowed to be on an equality with the three varieties named. We have often heard it remarked that a Barb is only at his best when he is half decayed, and that you see all of him at a glance. He squats in his pen all of a heap, and has none of the ever-varying motions so charming in a Pouter or Fantail, the fine attitude of a good Carrier, or the dignified strut of a Short-face. Barb hens were only five, and Mr. Bryce was first and third with Yellows, the former of a sound colour throughout, but the latter smoky blue in rump and tail. Second went to Mr. Laurie's Dun, a nice one, and of that glossy, hard, dark Dun only seen in Barbs, and so different from the Carrier Dun.

In *Trumpeters* Mr. J. E. Spence showed and won with an all-black Scotch-bred Russian, a really splendid bird. We should think his rose would be  $1\frac{1}{2}$  inch in diameter, and his hood if measured along the ridge following the semicircle at least  $4\frac{1}{2}$  inches. He was a particularly upstanding bird for a *Trumpeter*, showing his lines beautifully and not struck all of a heap like so many of them. The other was a Mottle—there were only two of them—but in no degree to compare with the Black.

**Fantails** were twenty-three and well judged, considering the Judge sympathises with the English style, but now so many Scotch birds have large tails and plenty of motion as well, the big tail alone, with nothing more, cannot win. Whites seem the favourites, and the class was chiefly composed of them, but

there was an all-black and two saddle-backs, one of which, No. 798 (W. Nelson), was a Chequer so nearly black as to be taken for it, and as clear-out as a Turbit. For motion, constant, and grotesque, we have not seen the like of this one for many a day, and we think the coloured sides are an additional property, just as a shouldered Turbit is superior to a White.

**Jacobins** contained twenty pens of Blacks, Reds, and Yellows, and were nearly all of the maned style. We saw some of them examined, and the plucked backs of their heads exposed. Without believing that the Jacks of the day have been crossed—for we have always considered the Reds and Yellows proverbial for richness of colour, and cannot imagine where this could come from—we are rather inclined to the belief that the manes are merely the result of selection. We bred them years ago, and found the big coarse ones often came so, and always considered that it resulted from the feathers lying the wrong way. As for the plastered-down hood we consider it an abomination, and as we have heard it remarked by good fanciers, makes the bird at a little distance off look like a Bald-head.

No less than thirty-three *Turbits*, Black, Red, Yellow, and Dun, competed; but, strange to say, not a single Silver. First and special went to Andrew & Cunningham's peak-headed Yellow, good in colour and good all over; second a peaked Blue (M. S. Temple); equal thirds to Robert Miller and to M. S. Temple for a Shell-crowned Blue, the best in Turbit points in the lot we thought, excepting the shell, for we prefer the peak; fourth to R. J. McKinlay's peaked Red, good in colour and frill, but not so fine in head and beak.

**English Owls** nineteen pens, all Blues and Silvers, except one of Whites. As pointed out in this Journal some months ago, it was suggested that English Owls being so far behind Africans in all the properties of the breed, they were not worthy of support, but that in so far as the colour known as powdered blue, a beautiful and striking colour, is not found in Africans, it might be well to make a class for it till Africans or Owls equal to them could be produced of the powdered colour. Fulton's book, part nineteen, lately out, suggests something of the same kind, and no doubt this plan will be adopted some day. It seems strange how what are called English Owls, though palpably and plainly in many cases only coarse or crossed Africans, should continue to be encouraged by intelligent committees of shows, while the English *Trumpeter* has been quite ostracised. Of the nineteen pens exhibited none were powdered, and as there were some good foreign Owls in the Variety class the English Owls contained nothing to please the writer or those of his way of thinking.

Class 80, for common *Tumblers*, Self-coloured, contained twenty-one pens of pretty birds. First were glossy Blacks, second pearl-eyed Whites, third rich Yellows, and fourth equally rich Reds. The next class was for common *Tumblers*, Blue-barred or any other colour. We did not see any Blues, but the fourteen pens exhibited contained Black, Red, and Yellow Mottles nicely marked, and some Almonds.

Class 62 was a charming collection of twenty-one pens of *Beards* and *Balds*. We think scarcely anything could exceed the beauty of colouring and marking displayed in this collection, combining Blacks, Blues, Silvers, Reds, and Yellows.

**Antwerps**, any colour, were, as we have already said, eight pens, and *Dragoons* four pens. As they take in money and special prizes to the value of £5 10s. for 8s. that they contribute in entry money, we do not think these classes will be repeated, at least we heard some murmurs to that effect.

"Ring out wild bells,  
Ring out the false, ring in the true."

**Common Pigeons**, nineteen pens of what we learned in our early days went by the name of sods; all Blue or Blue-chequers, except a pair of Whites.

**Nuns** twelve entries, all Black except two Red; the latter not so good, however, as the Blacks, who carried off all the prizes.

Any other distinct variety nine entries. First 998 (E. G. Keay), Blondinettes, mostly lovely birds—fancy Pigeons indeed. Second 994 (W. Brydon), equally pretty petite foreign Owls, White; third (John Cowe) beautiful powdered Ice Pigeons, the colour of a tropical moonlight with creamy bars; and fourth (J. Allan) nice sharp-out Magpies.

The **Selling** class, not exceeding 40s. for a single cock or hen, contained a miscellaneous assortment of twenty-three pens. A Carrier cock, No. 1019 (G. Brown) carried off first prize; a bad-coloured Red Pouter fourth. We did not see many birds marked as sold, though good value was to be had.

The concluding class, No. 69, was a **Selling** one for a single cock or hen not exceeding 30s. Thirty-two were entered here, and a Barb cock secured chief place. There was a good "old style" Yellow Jack, very much like Hutton's portrait, which we were told had been claimed by Mr. Huie. There was plenty of good value in this class also, but few marked "sold." Probably as closing time drew near more business was done.

**SPANNERS.**—1 and cup, Willoughby & Parvia, Hestham. 2, E. Jackson, Finchfield. 3, W. McIntyre, Oshliffe. 4, J. Ross, East Gatehead. 5, W. Outhbertson, W. Wallace, D. McBeath, J. Edgar, 6, E. Begg.

changed places. In hens or pullets there were eleven entries, the winner a very good hen of much excellence in all points. Second a promising pullet: 1545 (Fitch) a prettily-coloured bird, but poor in feet. Piles were a nice lot, and Mr. Fitz Herbert showed a good team of birds and did well with them. The winning cock is yellow-legged, and a splendid one too. Second a good adult cock, and third a fair cockerel. In hens or pullets we much admired the second-prize pullet, and thought perhaps a card might have been placed over her master's hen. Third another very good hen. 1565 (Stabler) a good old pen requiring more time. Black or Brassy-winged made up only six pairs, three of which belonged to Mr. Montessor. The first went to Black chickens, the other colour taking second and third honours. The same gentleman's other pen (unnoticed) was a smart pair of Blacks, the hen being especially good, but her mate failed in feet. In the undubbed Game class a smart Brown Red cockerel won the cup, but we did not quite like his colour. Second and third also went to Brown Reds, of which the former was a very nice bird in all respects. Seven birds were commended in this class, of which perhaps the best were pens 2414 (Fitz-Herbert), a Pile, and 2405 (Cameron), a capital Brown Red.

**MALAYS.**—No less than seventeen pens were entered. Mr. Hinton won the cup and first prize most deservedly. The cock is a superb bird and in grand feather. Second went to a capital pair of old birds of very even and sound colour; and third were a younger pair, very good, and of true Malay shape. Miss Brooke's was a nice pen and the colour was good. Mr. Burnell's pen were fair, and not dear at 50s. There were no less than seven pens empty, including those of Messrs. Payne, Falle, Perry, and Brownlie. We never saw so many empty pens in many of the classes at the Palace as on this occasion, and wish a mark could have been put against such tenantless pens in the catalogue for the edification of absent readers.

**SPANISH.**—These made classes better in numbers than quality. Of the four lots we thought the pullets best. The winning cocks, however, were all good. The first-prize bird also won the cup; he has a fine face of good colour. Next to him we liked the only highly commended bird in the class, for his lobes were very first-class. Hens were all backward; they will be in grand form by Bristol; as they were, many looked pinched and untidy. The cockerels were fair, nothing very grand anywhere, Mr. Chilcott's perhaps the best. Pullets made an improvement; the winner was nice and will improve yet. Second was a splendid bird with a beautiful face, and would have been first we should say easily but for her twist. Third certainly of great promise. The highly commended birds were, many of them, capital. Of them perhaps pens 1054 (Jackson), 1068 (Goddard), and 1070 (Chilcott), were as promising as any.

**POLISH** were very good. The varieties are putting in a capital appearance. The Golden-spangled were especially good, and really there were a dozen pens worthy of prizes which only had "highly condemned," as some jocosely term them. The winning old cock is a wonder in all points and was looking well. Second also a grand old cock, his crest and wings being especially good. Third went to a nice chicken promising to make a good one. All the noticed birds were good, and the Judge rightly called it "an extremely good class." Hens again were beautiful. The old winner looks splendid and won the cup; we never saw a better crest, and she has really moulted out as fresh as a daisy. Second good in colour, but not so perfect in crest as some of the other birds, still of great excellence; and third another really good bird. This class won the title of being "extraordinary," and the birds were certainly a superb lot. We believe Mr. Boothby lost his hen for £10 10s.: we say "lost," because we should say she was a bargain at the money. Silvers were also a very fine lot. We liked the winner in cocks very much. He wants more time, and will then run in as nearly the best old Polish cock extant we should say. Second was a good bird of immense crest and prettily marked—a good second. Third a very smart-looking bird, but not quite so all in colour. Hens were very fine, and Mr. Adkins indeed did well; his crests are very beautiful, and his hens have all such good markings. Mr. Hinton's hen was very fine, but her markings are not quite our fancy perhaps. Mr. Beldon's was a splendid hen, and almost deserved a better place. White-crested Blacks were very beautiful, but we were sorry to find so many pens disqualified. It would be well to know what amount of trimming is allowed, for we can but believe that every bird of this breed that wins has a certain amount of it. The winning cock was an old bird, a fine fellow, but his crest is not ready. Second, a very nice bird with neat crest. The third bird we liked the best of the lot; he is a fine cockerel with a grandly coloured crest. Mr. Norwood's bird was a pretty cockerel, but ordinary cockerels have no chance against old birds in this breed. Hens were very nice, the winner singularly good in crest and colour, and well first; second a very well-grown pullet of good colour with a large crest; third a beautiful hen with fine crest. Of the disqualified birds we will say nothing.

**SILKIES.**—The judging here was good, and we were pleased

to see all the prizes given to one type of bird, for crests, ears, and combs prevailed before mere perfection of leg-feather. The winning pair contained Mr. Woodgate's cockerel first at the Alexandra Palace, which was claimed there, mated with a very fair pullet. Second were beautiful in shape and head, but the cockerel's neck was full of pen feathers, which made him look a little yellow. Third a very nice even pair all round. Mr. Broad's old bird had a charming comb, one of the very best we ever saw, but the legs are in a bad state. 1695 (Holmes) a very nice pair, well-feathered, but a shade coarse-looking.

**LEGHORNS.**—We did not think the Browns so good as they were at the Alexandra Palace or Oxford, though perhaps many of the birds were the same. The winners, we are told, are imported. They are very nice in colour, and have beautiful lobes, but lack somehow the smartness of their English relations. The second were a nice pair, but we thought the cock carried his tail badly, and we preferred perhaps the third, where the cock was a fine bird, or even the pen of Mr. Mannock, 1669. Mr. Kitchen's birds were not, we think, his best, as we have seen better specimens of his at other shows. We can sympathise with him in having to fall back upon attendants to choose his birds for exhibition in his temporary absence from home. His birds in pen 1671 were extremely good in ears and colour. Whites made up eight pens, in which the colour was on the whole pretty even. The winners were well in first, and are very showy. Second not so good in colour, but still a smart pen. Third belonging to same exhibitor, and much resembling his second-prize pen. Mr. Fowler's were nice birds, and so were Mr. Day's, but they did not seem so large as the winners.

**ANDALUSIANS.**—This was the first venture here for this breed, and eleven pens were entered, of which half a dozen came from Miss Arnold. This lady won first and second with two nice pens, both of which contained very beautiful cockerels. Third went to a nice pen of adults belonging to an old admirer of this breed.

**VARIETY CLASS.**—This was extremely good. A very splendid pen of Black Minorcas, as good as any we ever saw, were first; fourth prize also went to a very good pen of this breed. Second prize was won by a fair pen of Cuckoo Cochins, and third nice White four-toed Sultans. 1711 (Harris), Black Malays of great lustre.

**THE UNTRIMMED CLASS.**—Very early on the first day we found ourselves in front of Class III, and we waited for the awards with much interest and great curiosity. We judged the class before the cards were up according to our own ideas, and could then only pity the people who had paid their 7s. 6d. each, and had no chance of the prizes by not sending vulture-hooked specimens. We were amazed later on when the awards were out to find that the Judge had evidently not thought more of hooks than any other point, and had given the prizes to the best birds in the class according to his ideas. The birds that won were a very beautiful Spanish cockerel, second a good Dark Brahma cock, and third a fine Dark Brahma hen (hooked). The class had twenty-eight entries, and we saw among them a Crève, Malay, a Spanish, and a Bantam. In Asiatics there was a good White Cochins cock, some fair Buffs, and one or two good Brahmas. We left the class regretting very much that it had not been called "the class for vulture-hooked Asiatics," when all the unpleasant words about it would have been spared; and we cannot help thinking that even after the schedules had been issued this class could have been set right by a few lines in the poultry papers; for though the disturbance did not arise till the entries were closing or had closed, considering the circumstances a week's act of grace could perhaps have been given to this class. As it was, the Judge acted undoubtedly wisely in keeping to the class as advertised in the schedule, and making hooks no more a *sine quâ non* than any other feature.

**WATERFOWL.**—The Aylesbury Ducks were very good. They were in pairs where Mr. Fowler's truly wonderful pair were again first. Second were also good, having splendid bills. Third a nice pair. Fourth were also good, and better matched, perhaps, than the third. Rouens were divided as to sexes, Mr. Evans did well. His birds are simply perfect, and splendidly shown. We never saw larger specimens, and congratulate their owner on his winnings. Second and third drakes both good and of large size. All the noticed pens were good, and would have come to the front well in any ordinary competition. Blacks made an immense class, of which Messrs. Kellaway and Sainsbury sent no less than ten pens. Mr. Kellaway had all his four pens in the list. We really cannot criticise the class, for we could never get the lot into equal light; but we may say that Mr. Sainsbury's Ducks were perfect beauties, and we do think the prizes should have been more divided between Devizes and the Island. Black Ducks, however, are dreadful things to judge, and we never envy anyone this work. Mr. Walker's drake is a beauty; what a pity he cannot buy a small Duck! And Mrs. Hayne's and Mr. Serjeantson's, though possessing much colour, are too large for the fashion. In fancy Ducks, Spotted Bills, Mandarins, and Carolinas won the prizes. They were all in lovely feather, and we can never make out in

such even company what the Judges go upon. Geese were splendid. Mr. Fowler once more to the front. Second went a cheap pen of Greys, and third to really good Whites.

TURKEYS had three classes. The quality was very even, as most of the specimens huge. The 1875 birds were especially good, and very well grown birds, calling to remembrance pleasant thoughts about the winning season.

The Sale classes were so immense and the quality so mixed that we could not attempt to go through them, especially; the remarks would hardly be of interest, so many of the birds having gone to fresh owners; but we must say one word about the first-prize Buff Cochins in the cock-and-hen class. The pullet is a wonder, the cockerel not worth a crown. We wonder if she will shoot hooks or a tail. We hope not, for she has got to a new home for £14 14s., and the lady who purchased her one who has striven against many difficulties honestly to come to the front in this fancy for which we all have so many pleasant feelings.—W.

**HAMBURGHES.**—As a rule the five varieties of Hamburgs are kept much in the hands of their old admirers and exhibitors still we rejoice to see some new names in their class, and these too, in the prize list. The cup for the best cock went to Golden-spangled bird, that for best hen to a Golden-pencilled and we think both the awards good.

**Golden-spangled cocks.**—The first class indeed. The cock bird was, we saw, marked sold, though ten guineas was his catalogue price. He is as near perfection as possible; his sickle flowing in an elegant curve, and his comb such as is rarely seen in spangled birds, ample, yet free from coarseness and beautifully spiked. Second a very good bird too; the peak of his comb not quite straight, and he has not the wonderful style of No. 1. Third a pretty bird with good carriage, but showing white edge on the breast and thigh feathers, so often taken off, and a slight blush in the lobes. Hens were in many cases out of condition, and we did not think the class a remarkable one. First was a bird showing traces of age on the head and back—viz., white-edge feathers. She is very round, and large in spangling. Second another old bird, small, and not bright in comb; her spangling glossy and even but not very large. Third a bird of very rich ground colour. We liked Mr. Pickles' highly commended bird.

**Silver-spangled cocks.**—The first-prize bird was certainly not equal to the Golden winner. His comb is large and a trifle coarse, but honestly shown; his spangling large and very green. Second a well-shaped bird with smaller spangling, particularly well marked on the wings. Third a less heavily spangled bird and too light towards the thighs. In spite of the present taste for very heavy spangling, we must say that we like to see spangled and not a black breast. The very highly commended bird (Pickles) in this class took our fancy. Hens.—No 1, to our ideas, a perfect bird, good in form and condition, with round and even spangling. Second a very nice bird which would mate No. 1 well. Third had large spangling, but not so clear in tail and not so elegant in carriage as the former two. Mr. Carr's very highly commended and highly commended birds were both good specimens of the lighter spangling.

**Golden-pencilled cocks.**—First was a lovely bird, perfection in colour, with good lobes, and excellent in carriage. Second in most points equal to the first, but rather too copper-coloured in tail. Third a smaller bird, good in carriage and lighter in neck hackle than the other prize birds. Hens.—First the cup bird beautifully barred and coloured, a trifle deficient in comb. Second also very well marked and good in colour, but not so clear in neck hackle and not good in comb. Third a heavily barred bird, a little mossy on the wing. The very highly commended bird was also good and heavily pencilled.

**Silver-pencilled cocks.** First was a pretty little bird, good in carriage, with an honestly shown comb but barred sickles. Second we preferred on the whole to the first; his head and comb are excellent, and he has beautiful flowing sickles. Third not a bird of the same style, somewhat squirrel-tailed, with one sickle not well grown. 1852 (Webster), commended, is a promising bird, but still very young. Hens of the Silver variety are as a rule rather more heavily pencilled than we like. First a pretty and well-formed bird with this heavy marking. Second good in lobes, too dark on the back. Third lighter in pencilling and deficient in breast-marking, which must have pulled her down.

**Black cocks.**—First a beautiful bird, in which we could see no fault. A faultless comb in a Hamburg cock which is, as in his case, also evidently as Nature made it, is a great beauty, and should receive its reward from a Judge. Second good in colour but coarse in comb. Third a glossy nice bird, which we were sorry to see ill on the third day. We liked the carriage of 1871 (Simpson). Hens.—First very good in colour and form. We observed in her a peculiar blue rim round the lobe, almost like that of a Silky; we have seen it in other Black Hamburg hens but never to the same extent. Second a neat bird, not a bad match for the first. Third very fair, rather pale in comb. 1864 very highly commended (Maxtor), a blooming bird, spoiled by a

Newcomer.—Marked Yellow.—L. W. Jackson, A. T. Newbold, J. Dent, & C. G.

JUDGES.—Poultry: MR. E. HEWITT, Birmingham. Cages Birds: MR. G. J. BARNESBY, Derby.

### HINCKLEY PIGEON AND RABBIT SHOW.

THE Show was held at Hinckley on the 17th and 18th inst. in the Corn Exchange, a room too small for the purpose, though held at the same time as the Crystal Palace Show, yet the entries were very good. From some cause the pens (which were from Whitwick) did not arrive, and this upset the whole of the arrangements, which seemed otherwise very good.

The Pigeons were placed in a very good light on the top of the Rabbits, which in some cases were rather difficult to see. Posters: the first going to a White cock of great size, with good hump, and (as we sometimes hear it put) "at the right angle;" second a well known Blue hen, which to be seen is to be liked; third a White cock, a little flat, but otherwise good; very highly commended a large Blue, but thick in girth. Carriers, first a Black cock, second a Dun, and third Black; very highly commended a grand Dun hen, a spout seemingly recently cut. Dragons a splendid lot, the first Yellow, second Blue, and third Yellow; six very highly commended, all well worthy of prizes. Antwerps, Short, were very good, first a Red Chequer, as also third, the latter rather rough in girth; second Silver Dun, good, but rather thin in beak; very highly commended a handsome hen of that colour. Long-faced Antwerps were also good, the first a Red Chequer of rather slaty hue was of immense strength of head and beak, and was stylish for so large a bird; second also of that colour; and third a Blue Chequer, long and strong. Tumblers, first and second Yellow Agates, and third a Kite. The Variety class was a puzzle indeed, and two extra prizes were allowed, as also in the Selling class. First a Black Barb; second Almond Tumblers; and third a White Owl; extra second a very pretty Pouter; and extra third a Red Jacobin cock. In the Selling class were some very good birds. The first was a most perfect Spangled Ice; second and third Black Carriers; extra second a Black, and extra third Red Barbs; and altogether this was the best Selling class we have seen for some time. In the local classes our notes are all bad, except the Antwerps (which were very good), the Tumblers, and the first in Variety class, a nice Yellow Turbit.

For the money given the Rabbits were a very good entry—namely, 91 in seven open, and 10 in two local classes, 101 in all. There was but one class for Lops, and it would be much better if these were divided into at least broken and self colours, and there is no doubt but that this would pay well. In this class the first was a Sooty Fawn doe, 22½ by 4½, very good in style, quality of ear and dangle, and perfectly straight in leg, a point very often overlooked in the eagerness to get length of ear; second a Black doe, 21½ by 4½, splendid in shape, even, fine in quality of ear, carriage, and condition; third a Black buck, very large, 21½ by 4½; very highly commended a Black-and-white doe, 22½ by 4½, not in good order, and small; very highly commended Tortoiseshell, very bad order, 21½ by 4½; several others running about the same, all points counted, and we would just say these were measured reasonably, and not as to pull the ears out of their sockets, but just as if we had tried it upon ourselves for a quarter of an hour before commencing operations. Angoras were a nice class, the quality surpassing many shows we have seen of late, but the size was not equal to some. Himalayans were a moderate class, the winners, however, very good, the first especially, and this in the catalogue at £1. The Northampton first was highly commended, and has gone sadly back. Silver-Greys a fair class. First a smart sharp-silvered doe; second a buck, large, even, but a little coarse and mealy; third was, however, better in quality, but much smaller; very highly commended a very promising young Rabbit. The Dutch were a grand class, and every one noticed, and the three winners as correct as any three we have ever seen together. First a Black-and-white, second Tortoiseshell, and third Black-and-white, but quite young and small. In the Variety class the first was a large and good Belgian Hare, second a Silver-Orean, and third a Patagonian; very highly commended a young Belgian Hare, a good colour, but short of marking. The Selling class was

large, but there were not many of very high merit. First was a good young Silver-Grey; second a Lop, 20½ by 4½; and third a Belgian Hare. In the local class of Lops the winners were 21½ by 4½, and 20½ by 4½, respectively.

The Committee seemed very willing to do the work correctly, but with limited room and inexperience we saw some errors; but as a whole the Show was well conducted, and we hope to see a more extensive schedule of prizes and better accommodation at the next attempt. The prize and sale money was sent off by cheque on Saturday night.

Mr. Yardley won the point prize for Pigeons; and Mr. Johnson of Kettering the one for Rabbits.

#### PIGEONS.

Posters.—1 and 2, H. Pratt, Hampton-in-Arden. 3 and 4, W. Hottage, Northampton. 5 and 6, J. Martin. Carriers.—1, 2, and 3, H. Yardley, Birmingham. 4, W. Larkin, do. W. Larkin, A. Makins. Dragons.—1, R. Woods, Mansfield. 2, H. Yardley. 3, A. Makins, Liverpool. 4, A. W. Wren, R. Woods, F. W. Jennings (A. Makins), A. Patten. 5, R. Woods, W. Larkin, A. Makins. 6, R. J. Rowley. Antwerps.—Short-faced.—1, R. D. Gough, Wolverhampton. 2 and 3, A. Farndon, Hinckley. 4, H. Yardley. 5, H. Yardley, C. Gamen. Long-faced.—1, C. Gamen, Chester. 2 and 3, T. H. Strach, Ormskirk. 4, C. Miller. 5, A. J. Gamen.

#### RABBITS.

Lop.—Doe or Doe.—1, R. Woods, Mansfield. 2, H. Houghton, Potters. 3, W. J. Coley, E. Pepper, J. Hingham, T. & R. J. Full, J. Barber. 4, W. J. Coley (A. Makins). 5, A. Githens. Angora.—Doe or Doe.—1, R. F. Henson. 2, R. Houghton. 3, W. Larkin.

#### LOCAL CLASSES.—PIGEONS.

Dragons.—1 and 2, A. Farndon. Antwerps.—1 and 2, A. Farndon. 3, J. Trivett. 4, A. Farndon, J. Patten, J. Trivett (A. T. S. Laidlow). Tumblers.—1 and 2, A. Farndon. 3, J. Tomlin, A. Farndon. ANY OTHER VARIETY.—1 and 2, T. S. Laidlow (Yellow and Red Turbit). 3 and 4, A. Farndon (Columb and Carrier).

#### RABBITS.

Lop.—Doe or Doe.—1 and 2, E. Pepper, Hinckley. 3, G. Houghton. 4, R. Arnold, W. Chapman. ANY OTHER VARIETY.—1, E. Pepper (Angora). 2, G. H. Houghton, Cattle Hill, Hinckley (Himalayan). 3, J. H. Houghton (Belgian Hare). 4, T. S. Laidlow (Silver-Grey).

JUDGES.—Mr. E. Hewitt, Poultry.

BIRMINGHAM POULTRY SHOW.—As announced last week, the entries for the twenty-seventh annual Show at Bingley Hall, on November 27th, 28th, 30th, December 1st and 2nd, are over the average, and an excellent display in nearly every department is anticipated. The London and North-Western, the Great Western, and Midland Railway Companies have acceded to the wishes of the Council, and announce numerous excursion trains from most towns within a radius of fifty or sixty miles. The stock and poultry are due to arrive on Thursday and Friday. The special appeal for support from the town and district, which has been recently issued, has been fairly responded to; and, as subscribers of 10s. or 20s. receive 15s. and 30s. value in tickets, there ought to be no difficulty in maintaining the list at such a figure as will enable the Council to continue, if not to increase, the amount of their present liberal prize list. (Midland Counties Herald.)

### OLDHAM BIRD SHOW.

THE first Exhibition of Birds of the Oldham Ornithological Society took place in the Temperance Hall, Horseedge Street, on the 11th, 12th, and 13th inst. Upwards of £80 were announced to be given in prize money, besides several silver cups and a timepiece. Whether the whole of the money announced to be given away will be disposed of rests entirely with the promoters of the Show. Several of the exhibitors who were prize-takers in some classes were proved to have exhibited painted birds in the Golden-spangled Lizard class, and to such a disgraceful extent that to award them prize money would be encouraging them and offering premiums for spurious-coloured specimens.

No less than half-a-score birds in Class 7 were found to be : **HARVESTING HONEY—THE EXTRACTOR.**

No. 1.

A LARON majority of bee-keepers keep bees for the sole purpose of securing a profitable harvest of honey, often in complete ignorance of the best means to pursue to secure their object, and I purpose in this paper to discuss the methods now in practice, and if possible to show how a better course may be pursued. Beginning with straw skeps I fear I step at once on dangerous ground, as our friend Mr. Pettigrew will tell me I am decidedly wrong when I say they are a mistake, should be obsolete, and are fit only for a museum of apiarian antiquities, or for use by those persons who cannot be made to comprehend the meaning of the word "progress," or by those who are too nervous or cowardly to handle their bees. To such people it is perfectly immaterial whether they use skeps, boxes, or frame hives; all are sealed books to them. I write now for those who are desirous of learning how to make the most of the thousands of willing labourers who toil for them.

Fig. 101.

There are three primary things to be considered; firstly to produce honey, secondly to produce it of superior quality, and thirdly to sell it. Few persons are aware of the enormous

Fig. 102.

amount of honey that at times is in the flowers ready to be gathered, and the small proportion of it harvested by the bees

not that they are idle—far from it, but probably two or three days' work has sufficed to fill all the available space in the hive, very likely not much, for it may chance that the stock is prospering under the sway of a young prolific queen whose brood fills many thousand cells. In this case, as fast as a young bee emerges from its cell the latter is immediately taken possession of by the anxious workers, and filled with honey; the queen wanders disconsolately over the filled combs unable to lay her eggs, and if this state of things continues so long, in about three weeks half the bees have died a natural death, and there being but few young emerging bees to succeed them the stock becomes weak from over-prosperity, and when the next glut of honey comes, with so many home cares the bees are unable to take advantage of it. Now, the only way to ascertain this state of affairs with straw skeps is to turn them up and examine as far as one can the combs; but how many bee-keepers will or can do this? It is not impossible, but not one in a hundred will make the examination. The addition of a super or skep will to a great extent relieve the bees if they use it, which they will not always do. With frame hives the bees, whether they will or no, may be helped in a few minutes to their own and their master's profit; but I will come back again to this presently. Straw skeps are commonly used (I except Mr. Pettigrew's pattern, of which I have no experience) in a good season will not, I am sure, yield an average of 20 lbs. of honey, both run and super. I am perfectly aware personal skill and attention will often succeed better than this, but I speak of the returns of fairly intelligent men. If I select labouring men alone, 10 lbs. per hive would be too great an estimate; with frame hives and proper attention this might be greatly exceeded. It is true that at the late Crystal Palace Show Mr. George Fox of Kingsbridge, Devon, exhibited a glass super of 86 lbs. obtained from a common skep, but this was the only super of note from a similar source; although had as the season was frame hives sent many, yet the number of skeps in use greatly exceeds frame hives, as everyone knows.

Straw hivists are not the only people I have to call to account for not making the best use of their bees' labour. As exceptional returns from a single straw skep we are amazed at 100 lbs., from a frame hive 150 lbs.; but what should we say at 500 lbs.? and yet this has been exceeded in America by the use of the extractor, which is universal with large bee-keepers there. That our Yankee cousins are very oute nobody can deny, and with them bee-keeping is a trade, the traders all adopting frame hives, Ligurian bees, and extractors.

Fig. 101 is an exterior view of the prize extractor "The Rapid." Fig. 102 is the interior mechanism. *a* is a framework of wrought iron kept together by cross pieces on the top and bottom; the cross piece on the top has a short spindle working in a bearing on cross bar (*d*), which also supports the driving wheel (*c*), and on end of spindle is a pinion (*d*) which is worked by the driving wheel, by which means the whole is thus made to rotate. On the bottom cross piece of the frame is another short spindle (*d*), which works in a socket fixed to the bottom of the can, and thus completes the support of the frame. Instead of a level floor the bottom is coned, so that the honey runs clear of the machinery, and is let out by a treacle valve. *f* are two cages covered with wire net; they work on pins which form hinges. These cages

Fig. 102.

*h* are the pins on which the cage swings. I may conclude by saying every part is well galvanised.—JOHN HUNTER, *Raton Bisc, Baling.*

### OUR LETTER BOX.

**HARM RABBITS** (*A Subscriber*).—Write to Messrs. Baily & Son, 118, Mount Street, Grosvenor Square, London.

**CANARY SUFFERING FROM ASTHMA** (*M. Clarke*).—Your six-years-old Canary is in a sad state. It is suffering from asthma in anything but a mild form either, and when complaint will continue until death, which most probably will take place before the termination of winter. Brass-wired cages never

meet with our approbation for Canaries. The wires become corroded when moisture gets upon them, and if the birds peck at the poisonous corrosion injury ensues to them. Why thus jeopardise the life of a pet bird? On the other hand, we are not going to say that in the case of your afflicted bird that its illness has been brought about entirely owing to its having been kept in the brass-wired cage. Canaries are liable to asthma even when kept in cages otherwise wired. Generally asthma is the result of cold caught when the bird's blood is in its worst state—when moulting. At this stage they require protection from cold draughts of air. The bird being kept where gas is used is warm at one time, and cold and chilly during the night. To endeavour to effect a cure it appears you removed the bird from the elevated situation it was in to one upon the floor, which is always the coldest part of a room. By so doing you certainly encouraged a greater difficulty of breathing, for the bird being ill at the time required warmth and better nursing. Remove the bird into a position midway between the floor and the ceiling, and keep the cage covered over, except the front, during the day, and entirely during night. To the water fountain add a few drops of sherry; give a bread-and-milk diet, and half a dozen drops of cod-liver oil mixed with a little soaked bread when the water is squeezed from it, which will nourish your invalid. In the place of green food at this ungenial season supply linseed, some scalded rape seed, and a few groats. You may thus prolong life for a short time if you allow the bird to continue in its miserable state. Our cure, if such it may be termed, would be more speedy. We should put the bird out of its misery and replace it with another, for at the age of six years it cannot be expected to afford much further pleasure considering the state it is in.

**AMERICAN CHURN** (*A Subscriber*).—There is a shop at the Oxford Street end of Holborn which specially has for sale the American inventions.

**BEES** (*A Young Beginner*).—1. The fern will do very well, provided it is kept dry. 2. For the sheep hive you want write to Mr. Abbott, Hanwell, near London. His price is 6s. 6d. 3. It is a very good sign when bees take in pollen at whatever time of year. It is a sign that the queen is breeding. She lays eggs in winter as in summer when the weather is mild, although of course not in the same degree.

**FELT HIVE COVERS** (*Farmer*).—Roofing felt is 33 inches wide, and may be bought in lengths by the piece, or by the yard at 1d. per square foot, or 8d. per lineal yard. This is the highest retail price. In cold weather it is hard and stiff, but easily softened and made as pliable as flannel before a fire. When first used on a hive it should be softened, wrapped round and tied close to it with a string. It can be placed so that the whole hive is covered and the board overlapped, and thus shed-off every drop of rain. We have hives covered with felt that has been constantly used for ten years, and if it were retouched with tar or pitch might be efficient as a protection for another ten years. Felt is not an ornamental covering for hives, but its durability, convenience, and portability recommend it to us and all our friends who have used it.

### REMARKS.

- 17th.—Fine though hazy and cold in the early morning, but followed by a damp disagreeable day; the after part the best; wind rising at midnight.
- 18th.—Very fine all day; rather cloudy between 1 and 2 P.M.; but a starlight night.
- 19th.—Wet and cloudy till the afternoon, slight shower after; dark very early; windy night.
- 20th.—Very fine all day and all night.
- 21st.—Fine all day, but very much colder; stars at times very bright.
- 22nd.—Fine till 2 P.M., then a slight shower, and a damp though not rainy afternoon.
- 23rd.—Fine all day; white frost in the morning.
- A much finer week than we have had for some time. The mean 9 A.M. temperature nearly identical with last week, but the range much greater—for instance, the 20th was 19° colder than the 19th.—G. J. SIMONS.

### COVENT GARDEN MARKET.—NOVEMBER 24.

The Market is generally in a very dull state. Apples, Pears, and Quinces continue to arrive in immense numbers. French Asparagus is also arriving with liberal consignments of salading. Prices remain virtually the same as last week.

From observations taken near London during forty-three years, the average day temperature of the week is 47.8°; and its night temperature 31.4°.

## NECTARINES.

## THE RENOVATION OF OLD TREES—AN ESTIMATE OF SORTS.

**NEOTAR**, the fabled drink of the gods: hence Nectarine. The name is certainly as appropriate as it is suggestive, this fruit being especially notable for its delicious flavour, all the best kinds now in cultivation being more or less excellent in this respect; it is, however, excellence in degree, for even here we may not claim to have attained to full perfection. Pitmaston Orange is my standard sort for flavour. Taken at its best

when fully ripe and with a slight tendency to shrivel it is difficult to find its equal among Nectarines or any other fruit. It was placed first at the great Fruit Show at the Alexandra Palace in September, not because its fruit was finest, but because the Judges very wisely tested it and the larger fruit of Lord Napier for flavour.

Before proceeding to discuss the merits of some kinds, I wish to call attention to the renovation of old and exhausted Peach and Nectarine trees. By exhausted trees I mean those which are in such an enfeebled condition as to produce nothing but small undersized fruit. This lamentable state of things is more frequently owing to over-cropping and to injudicious management than to actual old age. There never was a greater mistake made than the modern advocacy of sensational heavy cropping of very young trees. Talk of "floricultural millinery," that is a trifle in comparison to the ridiculous extreme to which pruning, pinching, and cropping by line and rule have been carried. Take a young tree, plant it, stop its first growth at so many eyes or inches, cut off its toes—I beg pardon, roots—prune it, lift it; in fact, do anything that will prevent a vigorous growth, and cause it to form fruit buds so that you may be able to entertain the delusive fancy that you have a quick return and clear profit upon cash expended, if it be only a farthing the first year and three farthings the second. This is the form which such teaching really takes when put into plain language: if it is followed what is eventually the result? A crippled weakly growth, incapable of bearing fine fruit; and in any case the condition of the fruit is as unsatisfactory as is that of the tree. Premature decay follows, and the trees are then said to be short-lived; climate, soil, and tree being declared at fault rather than the cultivation. If we must have rules let one be that no tree shall bear fruit till the third year after planting.

There is no doubt that really old trees are often kept on year after year bearing fruit of inferior size and quality without any attempt at renovation or improvement. The remedy is plain, yet it is not always possible to apply it. One would, of course, like to adopt sweeping measures with such trees, but this is impracticable when it is imperative that there shall be an annual supply of fruit, no matter how indifferent its condition may be, and so the only plan is to take one or two trees in hand each year till the whole of them are gradually, almost imperceptibly, brought into a better condition. Now, despite all that

has been said about the tenderness and early decay of Peach and Nectarine trees, it is an indisputable fact that most old trees possess a wonderful amount of vitality, hardiness, and an inherent vigour, which, when the old worn-out branches are removed, bursts forth with such power as to quickly replace them with others of such strength as will rival the growth of the most sturdy newly-planted tree. Is there not a valuable lesson to be learnt here? It was not long ago that Mr. Wright pointed out most clearly how much the vigour of a Grape Vine was kept in check by its old knotty spurs, the hardened contracted tissue preventing the quick flow of sap—precisely that prompt and ready action which a brisk growth demands and must have in order to sustain it in full vigour and enable it to bring the crop to maturity. Just so is it with the Peach and Nectarine. When the main branches become bark-bound the action of the sap is so sluggish that the branches cannot put forth shoots of sufficient strength to produce fine fruit. Cut back the whole of those branches to within a foot or two of the bole, see that the roots are in a suitable medium, and in two or three seasons you have a tree re-invigorated, the growth young, vigorous, and fruitful, and the fruit itself of large size and excellent in the highest degree.

Mr. Rivers has greatly enriched our collection of varieties of Nectarines with his splendid seedlings, which, in addition to great intrinsic merit, have, by the earliness of some and lateness of others, materially lengthened the time when ripe fruit can be had. I have planted most of them, but all have not yet fruited. I have great hopes that Albert Victor, which ripens its fruit about the middle of September, will prove of much value, and should be glad to know the opinion of others who have fruited it. Pine Apple is the latest kind I have yet fruited; it proves a great acquisition, succeeding the mid-season kinds, and formed an admirable finish to the past season, which was so well begun by

*Lord Napier*.—This is a very fine kind, the branches, foliage, and fruit all being of an extraordinary size, much of the fruit attaining a circumference of 8 to 9 inches. Its colour when ripe is a pale yellow, with light red on the exposed side. The fruit is very handsome, and of delicious flavour. It is ripe in August—earlier than any other good kind.

*Pitmaston Orange*.—A distinct sort of the highest excellence. The large oval-pointed fruit is finely coloured—a bright orange, with deep crimson on the sunned side; the flesh is of a deep orange colour, with a tinge of crimson next the stone. It is very sweet, rich, and juicy, surpassing almost all other Nectarines in its exquisite flavour and fine aroma. The growth of the tree is not quite so vigorous as most others, but it is perfectly healthy, and I have no hesitation in giving it the prominent and leading position of which it is undoubtedly most worthy.

*Downton*.—A very fine Nectarine. The fruit, which is produced in great abundance, is very handsome, large, with the skin of a deep crimson hue; the flesh is melting, rich, and very juicy, with a brisk acidulous flavour that is most

refreshing. The tree is very robust, and it is altogether a first-class kind. I have an impression that this excellent variety has been somewhat neglected. If I am right I would strongly recommend all, who can afford space, to plant it, for it is worthy of a place in the most choice selection.

**Balgowan.**—This is another fine kind; a note of it in my fruit book for the current year states that it is "a tree of wonderful vigour, laden with an abundant crop of fine large fruit, beautifully coloured, very sweet, rich, and delicious in flavour. A valuable variety." The growth of the tree is certainly something wonderful, surpassing all other kinds that were planted at the same date. It is usually described as a very hardy kind, but I have observed a greater tendency to canker in it than in any other Nectarine which I have.

**Rivers' White.**—A good and very useful sort, cropping freely. The fruit is of a pale yellow colour, sweet, juicy, and of pleasant flavour. Especially valuable for its colour. The tree is vigorous and healthy.

**Stanwick Etruge.**—This is a very prolific variety, but the fruit was decidedly inferior in appearance and flavour to all the foregoing varieties during the past season. It is only fair to add that the crop was a heavy one, which would in some measure account for its deficiency in points of so much importance as size and flavour.

**Pine Apple.**—This splendid variety may very justly be termed a late Pitmaston Orange, and as such is of the greatest value, for in it we have a most valuable succession to the general crop. The fruit is very handsome in form and colour, and surpasses most of the other Nectarines in size and flavour, which is wonderfully full and rich. Unlike Pitmaston Orange, my tree is very vigorous, and promises well for another season.—EDWARD LUCKHURST.

#### GRAPES NOT COLOURING.

I HAVE a vineyard glazed with Hartley's patent ribbed glass, and I have been informed that Grapes seldom colour under it. I am at a loss to tell where to blame this failure, whether it is the glass, border, or the past treatment. The Vines at present are in a fair condition, and have this year borne a heavy crop of uncoloured Grapes. The varieties are Black Hamburgh and Trentham Black. The Trentham Blacks are as well coloured as can be desired, while the Black Hamburgs in the same house are as red as a fox. I intend renewing the border to see if that will remedy the evil. I shall be glad to hear the opinion of some experienced Grape-growers. I may mention that a gentleman near has a vineyard glazed with the same kind of glass. The Vines planted are the Black Hamburgh, and are healthy and vigorous, and were carrying when I saw them a good crop of large, well-formed bunches of badly-coloured Grapes. The complaint there is the same as my own.—E. H.

#### THE ROSE ELECTION—ROSES AND NOSES.

I TAKE now the concluding portion of the Rose election for 1875, that of perfume. This is a novel attempt; I am not certain that it is successful. Electors, not a few, appear to distrust their nasal organs, and others confess to a want of education of these organs as connected with Roses. Although "a Rose by any other name would smell as sweet," yet it would certainly appear that not a few Rose-growers allow her in some degree to "waste her sweetness on the desert air." There is little doubt that Rose-growers for exhibition look at a Rose twenty times before applying to them that organ for which in the "Eyes versus Nose" of Cowper, "the spectacles" were really intended. Few rosarians can lay claim to such an educated organ as Mr. Curtis, Devon Rosery, Torquay; and if the wise men came from the east, at least it seems to me that the appreciators of Rose perfume dwell in the west, for Mr. R. W. Beachey and Mr. Curtis are the only electors who appear to have analysed the various perfumes that our national flower possesses. This, their lists, the only lists of perfume I shall print, sufficiently prove.

In undertaking this election I was prepared for some extraordinary results. In my weakness I fancied the old Cabbage Rose must be near the head of the poll; but it is far from that, and I can only imagine that many electors have never had the opportunity of testing the merits of this delicious old Rose. Let me, however, first present the poll—premising that as only twenty electors have ventured to give their opinions on this point, I have mixed the two classes of electors together, believing that there was nothing to be gained by the separa-

tion, and that one class of nose was just as good as another. The first column of figures, A, denotes the number of times each Rose is named in the first twelve; the other, B, the votes in the second thirteen; whilst the last column shows the number of votes each Rose received.

A & B Total				A & B Total

22	Mlle. Marie Badé	3	4	7					
23	Julie Margottin	3	4	7					
24	Madame Forté	5	2	7					

Here is a table that I feel confident will excite some surprise. La France alone nearly achieves a first-class certificate all round, only one elector giving her a second-class vote. It has not been my custom hitherto to mention these eccentricities of electors; I have no scruples on this occasion, as that second-class vote was given by the returning officer, and I now confess openly that I fail utterly to detect in La France the exquisite perfume that most others note. Well, I suppose it is my loss, but I certainly did not calculate that I should be the only person to place that Rose in the second class.

By the twenty electors, with only twenty-five Roses named, the Roses named in this election amount to 154. This is startling enough; but amongst the twelve best, ninety-two Roses actually find a place. Yet again another curiosity: Out of the 154 Roses mentioned, no less than seventy-seven—exactly one-half—have only a solitary vote, and of these seventy-seven no less than thirty-four, though named only once, are yet considered by the nominator A1, or amongst the best twelve, showing at least that there is as great a difference in noses as in eyes, having only one vote. All the electors are nominators of Roses.

I may here mention the electors who have assisted at this election by sending in lists. They are Sir William Bagge; Revs. A. Cheales, J. B. Camm, E. Handley; Messrs. Baker, R. W. Beachey, H. Bennet, Blandford, Cooling, Cranston, Curtis, Davis, J. Ellis, Harrison, Hinton, G. Prince, Robson, Scott, Turner, and Wheeler; and to these gentlemen, and in fact to all who have in any way tended to make these elections either useful or interesting, I tender my sincere thanks.

Mr. R. W. Beachey's list and that of Mr. Curtis I append; the other lists are in the next column. The Roses in italics are those

value and usefulness over the scentless beauties of which we have now so many!

In giving this short arbitrary list of twenty-four it is painful to have to exclude so very many of perhaps equal merit, especially among the Teas and high-coloured Perpetuals.

1, *La France* (Hybrid Tea scent).—The most deliciously scented Rose known. Its fragrance is even more remarkable under glass than out of doors.

2, *Maréchal Niel* (Sweet Tea scent).—Very full, rich, and fruity.

3, *Devoniensis* (Sweet Tea scent).—This and *Socrates* are, perhaps, the two most powerfully scented Roses we have, though not strictly speaking the sweetest.

4, *Goubault* (Sweet Tea scent).—Peculiarly sweet and powerful.

5, *Charles Lefebvre* (Otto Perpetual scent).—Combining an idea of otto of Roses with the old Perpetual.

6, *Madame Knorr* (Otto Perpetual scent).—This like *La France* is most remarkably sweet under glass.

7, *Bessie Johnson* (True Hybrid Perpetual scent).—Very fine and deliciously fragrant.

8, *Aline Sisley* (Fruity Tea scent).—Very striking, resembling the peculiar aroma of Black Currants.

9, *Souper et Notting*, H.P. Moss (Provence Rose scent).—This quite eclipses the old Cabbage scent, uniting with it the richness of the Moss Rose.

10, *Céline Forestier* (Sweet Tea scent).—Emphatically so.

11, *Madame Furtado* (True Hybrid Perpetual scent).—Partaking somewhat of the otto.

12, *William Jesse* (True Hybrid Perpetual scent).—This old Rose may be called the father of this class of scent. Many Roses with its lilac tinge partake also of its fragrance.

13, *Socrates* (Fruity Tea scent).—Nectarine-scented, very powerful and distinct.

14, *Gloire de Dijon* (Fruity Tea scent).—Very sweet and rich.

15, *Narcisse* (Musk Tea scent).—Reminding one also of *Primroses*.

16, *Eugène Desgaches* (Aromatic Tea scent).—This is said to slightly resemble the peculiar odour of Sandalwood.

The following varieties have true Hybrid Perpetual scent:—

17, *Pierre Notting*; 18, *Comtesse de Chabrillant*; 19, *Baronne Louise Uxkull*; 20, *Alfred Colomb*; 21, *Duke of Wellington*; 22, *Antoine Ducher*; 23, *Richard Wallace*; 24, *Madame Victor Verdier*.

Although not belonging to the above set of large type flowers, I cannot close my list without mentioning two delicious little early gems—the *White Banksia* (Violet-scented), and the *Double White Scotch*, with a peculiar kind of otto scent. They are in bloom out of doors several weeks before the above, thus lengthening our sweet Rose tide.—HENRY CURTIS, *Torquay*.

In naming twenty-five Roses for fragrance I suppose the Hybrid Perpetuals and Teas must claim the lion's share of attention, just as they have usurped (and rightly so), the lion's share of our gardens and greenhouses. By the way, did anyone ever enjoy the full fragrance of a Rose who has not caught it under glass just as the first rays of the morning sun are gently warming its petals and tempting it to open its sleepy eye? I fancy not. Certainly I never had such entrancing whiffs from Rose paradise as when I stole a few moments from my quiet half hour before breakfast to take a hasty look round the greenhouse some bright April morning. After breakfast would have been too late. You must let the sun pull out the cork from your bottle of otto of Roses right under your nose, and then!

I have an idea that the H.P.'s and Teas may be divided into four distinct classes, each one giving a perfume of its own. Of course these might be again subdivided, but four are sufficient to mark the main characteristics of each. These, with a few Roses other than H.P.'s and Teas, will in-  
y of notice.

gin with the H.P.'s. These naturally divide into two classes, the first containing the dark crim-  
maroon, and crimson Roses. The fragrance of  
nite distinct from that of the lighter varieties.  
be a richness and body in their perfume which  
; while at the same time they are not so sweet  
lighter Roses.

class embraces the lighter H.P.'s, such as *La  
brand*, &c. These are sweeter than the former,  
the peculiar otto fragrance. Is it not strange

that so few of the medium-coloured Roses (the true Rose colours and carmines), are highly scented? I do not know of one that can fairly be called very sweet with the exception of *Madame Derriex Douville*. *Edward Morren*, *Marquise de Castellane*, *John Hopper*, *Victor Verdier*, and most others of the same shade have hardly any perfume. Can anyone account for this?

Then we come to the Teas and Noisettes. These also one may divide into two classes: First, the sweet Teas, partaking more of the Tea than of the China perfume; second, the astringent Teas, partaking more of the old China scent than of the Tea. These latter are quite peculiar. One can scarcely call them sweet at all, and yet they are refreshing and pleasant, slightly pungent and aromatic.

Into the fifth class we will put those good old Roses that scarcely dare now to show their flowers except in cottagers' gardens and old-fashioned places. But we must give them a place here, for who can deny that they are sweet, though homely?

Class I. Maroon, Dark Crimson shaded, and Crimson H.P.'s (Otto-scented).—*Louis Van Houtte*, best of all; *Ferdinand de Lesseps*, *Princesse Camille de Rohan*, *Pierre Notting*, *Charles Lefebvre*, *Alfred Colomb*, and *Camille Bernardin*.

Class II. Lighter-coloured H.P.'s (Sweet-scented).—*Madame Derriex Douville*; *Madame Knorr*, delicious, something like "old Cabbage;" *La France*, sweetest of all; *Elie Moral*; *Abel Grand* and *Bessie Johnson*, same perfume.

Class III. Sweet Teas and Noisettes (more Tea than China).—*Maréchal Niel*, richest; *Devoniensis*, sweetest; *Gloire de Dijon*, *Céline Forestier*, *Madame Margottin*, and *Souvenir d'un Ami*, on the border.

Class IV. Astringent Teas (more China than Tea).—*Goubault*, good; *Catherine Mermet*, and *Socrates*.

Class V. Roses other than H.P.'s and Teas.—*Old Cabbage*, *Double Scotch*, *Banksian*, and *Common Moss*.—R. W. BRACHET.

#### MERITS OF PEARS.

THE crop of Pears this season has been remarkably good, and perry is consequently cheap, but my notes refer more particularly to dessert Pears, of which we grow a great many varieties. As soils have a great influence on the growth and merits of the Pear, I may state that our soil is light and sandy on a sandy subsoil.

The following are the varieties which I have found to suit us the best:—*Williams' Bon Chrétien*, good crops, fair sampler, and good flavour, on espalier; *Beurré d'Amanlis*, espalier, crop very heavy, large, and fine; on pyramid the crop was also heavy, but fruit not quite so large, and some of them were a little spotted. *Fondante d'Automne*, pyramid, crop very heavy, and fruit very sweet and juicy. I find it keeps longer if gathered a little before it is quite ripe; it is not then so liable to go at the core, and is equally as good in flavour. *Louise Bonne de Jersey*, crop heavy and fruit large and good in flavour, but it only kept about a week after being gathered. It is one of the best Pears of the season, and a sure bearer. *Beurré Superfin*, crop very good and likewise flavour, but some of the fruit a little spotted. *Marie Louise*, crop heavy, and the fruit on espaliers ripened a beautiful yellow; on pyramids not quite so yellow, but the trees were loaded to the ground, but the flavour is indifferent this season, and it did not keep long, nevertheless it is a first-class Pear. *Pitmaston Duchess*, a most noble-looking Pear, many of the specimens being over 1 lb. each; the crop is heavy, and it seems a very free bearer on our soil. I should like the opinion of others who have grown this Pear. *Beurré Diel* is a Pear which succeeds on our soil remarkably well, always producing good crops of beautiful-looking fruit without a blemish; *Triomphe de Jodoigne* also suits our soil well, the crop this year being heavy, and the fruit large and fine; *Doyenné du Comice*, a most delicious Pear, and succeeds best with us as a standard, from which we have the largest and finest fruit; *Knight's Monarch* succeeds well with us as a pyramid, producing beautiful specimens and heavy crops; it is a first-class late Pear. *Zephirin Gregoire*, good as a pyramid; crops this year heavy. *Swan's Egg*, first-class here as an espalier, each branch looking like a string of Onions; but the fruit is not so large as it might have been had we thinned them more. *Easter Beurré*, good as a standard, crops heavy, and the fruit without a spot; the trees are also remarkably healthy, but not so with pyramids and espaliers, for the fruit has been very much cracked and spotted, and many of the trees are also cankered and stunted

in their growth. I am of opinion that the stock on which this Pear is grafted has a great deal to do with its well-being. Will anyone give their experience on this point? I am inclined to say the Pear stock is the best, and allow the tree to develop itself. General Todtleben succeeds well as a pyramid, but the largest specimens were on espaliers. Hayshe's Prince of Wales is this season magnificent on espaliers, good specimens of fruit, and completely covered with very dark russet. No Plus Meuris, very prolific as an espalier, fruit rather small, but should have been thinned more freely. Bergamotte Esperen, first-class as a pyramid, being a sure bearer of delicious late fruit. Beurré Rance, good as an espalier, but the fruit on some of the trees has cracked badly. Is it general this season? Vicar of Winkfield, heavy cropper as a standard. We have a large standard tree which was left in the old kitchen garden here which is so loaded with fruit most seasons that we are obliged to support the branches with props; a good stewing Pear, and passable for dessert when Pears are not very plentiful. Josephine de Malines, good here as a standard, but so far it has been poor as an espalier, and the fruit small. Jean de Witte, a good bearer of medium-sized fruit, but many of them spotted this season. Louise Bonne de Printemps, crops good, fruit medium in size, and free from any spot. Black Worcester succeeds well here on espaliers, producing fine crops of large fruit; it is a first-class stewing Pear, a sure bearer, and keeps well.

The above are a few out of about sixty varieties that have this season carried heavy crops; the others have carried more or less, but those named have done the best. As I wish to add to my collection I should be obliged for a few notes from any of your correspondents who have a similar soil to mine. Perhaps Mr. Douglas would favour us with a few notes, for I fancy his soil and ours pretty nearly correspond. Pears I find are not keeping well this season; they are soon over when they begin to ripen, and the long-continued rains, with the absence of sun, has impaired the flavour of many of them.—J. A., Hill Grove, Kidderminster.

#### DIAMOND PEACH.

Mr. LUCKHURST does not appear to cultivate this Peach, else he would probably have enumerated it in his list as one worthy to be cultivated by even those who are restricted to two or three varieties.

It has three points to recommend it—First, it will set its fruit without protection better than any other variety; second, it is a moderate grower, devoid of those sappy shoots so common in other varieties; and lastly, it comes in between Early York and Royal George, and is, therefore, a great desideratum to all who have to keep up a supply of this luscious fruit from the open air. It is a variety that also comes very early into bearing, my own trees fruiting the third year from the bud, while other favourite varieties were barren. The fruit is of large size, beautifully coloured on the exposed side, and equal in flavour to other well-tried sorts. I believe it is an introduction by the Messrs. Veitch of Chelsea, and is worthy of more extended cultivation.

After marking results here and elsewhere, I can confidently recommend the following select list for outdoor culture:—Early Beatrix, Early York, Diamond, Royal George, Grosse Mignonne, and Noblesse. Can anyone recommend a variety later than the above-mentioned which would stand a chance of ripening in the midland counties? Lord Palmerston will not do so.

The soil here is very sandy with sand as a subsoil, therefore not at all suited to either Peach or Plum culture, but by rich mulchings and plentiful supplies of water during the flowering period I invariably secure moderate crops of fruit.—A. W., Heighington, Lincoln.

#### BRIAR STOCKS FROM CUTTINGS.

BEING recommended in the *Journal of Horticulture* last autumn (October 15th, page 389), Briar stocks put in as cuttings with a heel, I procured some which were inserted during November, and are now lifted with roots superior to anything I have seen on the Briar previously.

Having found the roots so superior to those made on the lifted stock, I venture to note the result, although I have not been so successful in the number struck as Mr. Turtle. Sixty-eight were put in, out to 8 feet in length. The budding was done in May. Thirty are now planted in prominent places

with nice heads, eight budded but have not made heads fit for planting this year, twelve unworked, and eighteen deaths, mostly owing, I have no doubt, to unripened wood, as the Briars were cut from the middle of thick hedges, not being able to procure them from positions more conducive to ripened wood.—R. O., Castle Gardens, St. Fagans.

#### DOUBLE CLARKIAS.

CLARKIAS are amongst the most effective and useful of our hardy annuals, and improvements in the colour and form of the flowers are continually being made. Double varieties have long ago been offered to the public, but these at the best have been but semi-double, and the plants generally have proved of loose habit. Examples, however, which were submitted by Mr. Hardy of Bures to the Floral Committee of the Royal Horticultural Society on July 7th, were undoubtedly *bond fide*

Fig. 104.—Double Clarkias.

double flowers, and as such they were awarded first-class certificates. The flowers were also closely arranged on the spikes, giving them a massive appearance quite dissimilar to the ordinary type of semi-double varieties, and suggesting their usefulness for affording cut blooms. The engraving gives a faithful representation of the spikes as then exhibited; and if the varieties prove constant they must be regarded as great acquisitions amongst easily-grown border flowers. Mr. Hardy exhibited them in two varieties—Purple King and Salmon Queen, and they have certainly just claim to be considered as reigning monarchs in the Clarkia world.

#### CONCRETING VINE BORDERS.

Mr. PRACH inquires whether the Vine borders at Arlinton and Potholm were concreted. They were not concreted, but they rest on a subsoil of gravel which is better than any concrete. A foot of drainage was placed in the excavation, and on this turves were placed with their grass sides downward to keep the drainage clear from the soil. At Potholm the bottom of the border before putting in the drainage was excavated in a series of diagonal trenches 4 feet apart, bringing the ridge between each to a sharp apex, and in each trench a row of drain-pipes were laid, having a sharp fall and communicating with a main drain at the extremity of the border. Drainage

was therefore provided for in the most effective manner. The bottom of the border when excavated was the exact counterpart of a ridge-and-furrow roof.

Now where concrete is necessary there can be no better base for it than these diagonal ridges and pipes laid between them. There cannot then—the falls for the drains being right and the outfalls clear—be any possibility of the border becoming water-logged.

I am of opinion that on a sandy or gravelly subsoil, or also on the sand or limestone formation where the subsoil is porous, that it is not necessary to concrete the bottoms of Vine borders. Provided the water can pass away freely concrete is not necessary; but where it cannot pass away—as in a bed of clay, for instance—then I should certainly have a ridge-and-furrow bottom concreted and drained, with an effectual outfall for the water which I should apply liberally in the growing season.

There is very little doubt but that Vines have suffered greater injury by drought than by water, and that concreting and drying the borders on a porous subsoil in dry districts has in many instances been carried to excess. Where Grapes are prone to shank it is worth while considering whether dryness of the roots is not one of the contributing causes. I am acquainted with a fine vineyard which every year produces many shanked berries, but in no year did I see them in a worse condition than in 1868, when the year's rainfall of the district was under 20 inches, whereas in 1872, when the rainfall was nearly double that amount, shanking was much less inveterate.

I do not dispute that shanking is fostered by a water-logged soil; but I suspect that the effects are not widely different whether the spongioles have rotted by wet or shrivelled by drought.

The Vine in its nature is a water-loving subject. Its rapid succulent growth, its expansive foliage, and, more than either, its juicy fruit, all cry aloud for water. I have very little doubt that if a Vine in its growing state—roots, wood, leaves, and fruit—were analysed, that 75 per cent. of its bulk would be water. If that is so its wants are clearly foreshadowed, and water it must have ungrudgingly if it is to flourish vigorously. The best proof that that is sound theory is the support which is afforded by actual practice. I have only been able to grow heavy crops of Grapes by heavy waterings in the growing season. But there must be efficient drainage. It is not primarily a question of water but one of drainage, for if the latter is perfect the supply of the former can scarcely be too great.

But the mechanical nature of the soil must be taken into account. Some soils are more retentive of moisture than others, and a weight of 20 inches of rain on one soil may in its effects be represented by 40 inches on another, and *vice versa*—that is, the drainage being the same in two instances the Vines in one border will need double the amount of water over those in the other, solely by the difference in the mechanical nature of the soil; and it is here that the intelligence of the gardener must be exercised. We may lay it down as a rule that the Vine is a moisture-loving subject; that it must have water liberally, but the precise meaning of "liberal" must be left to individual interpretation to be governed by the local circumstances of each case.

Concreting, I have said, is not necessary on a porous subsoil where water can pass away freely, and injury has often resulted by concreting on such soils. It is all very well to say that we concrete to prevent the roots passing into a poor unnutritious soil, but it must also be remembered that concrete not only prevents the roots descending, but it also prevents the earth moisture ascending. It completely arrests capillary attraction. The summer's sun cannot draw up the winter's rain from the reservoirs of the earth through a concrete roof, and by that cause alone Vines suffer injury in dry districts.

The roots of Vines when they pass into an ungenial inert medium are generally driven there; they are in search of food and moisture, which they cannot find near the surface. There need be no fear of injury arising to Vines by the descent of their roots into unsuitable soil if what they need is afforded them near the surface. They do not enter the inert soil because they like it, but because they penetrate it in search of the matter which they need, and the more such soil is deficient in the food of which they are in search the further will the roots ramify. The natural preventive is to supply food on or near the surface of the border, and if sufficient moisture accompanies it to render it soluble, then the roots will not

wander into bad soil and receive injury in search of what they need.

There are cases where concreting is necessary, but not to prevent the roots going out of their proper compost, but as a means of conducting superfluous water into the drains. I could give some instances of the use and abuse of concrete. I have this year seen the concrete of a Vine border laid bare, and on it rested 8 inches of water. The border was nearly on a level, and what drains there were had become choked by sediment. Sediment traps are exceedingly useful, but extremely dangerous. They are not uncommonly placed by the side of the gravel walk, under which the main drain—the Vine-border catchwater—is conducted. The loose gravel is washed through the grating, and is left in the sediment box until it reaches the level of the drain, and is then conducted into it; and thus are Vine borders, by neglect of timely and systematic attention given to the drains, made waterlogged by the very medium that was provided to keep them dry. I have had to take out two Vine borders which had become waterlogged by the simple matter of permitting the drain pipes to become choked with the surface washings of gravel, &c. In both these instances sediment boxes had been provided, but their contents had not been regularly removed, and hence the mischief. I know at this moment a Vine border which has become sour by the same means, and the border will have to be renewed before good Grapes can be obtained. It would have been far better that those borders had not been concreted and drained at all than that the drains should have been neglected. It is with good reason therefore that I say, Look to the drains.

I am well acquainted with a splendid range of vineries which had been erected, and borders made regardless of cost. The site was not wet, and the rainfall of the district is exceptionally low, yet these borders were concreted, and I believe they were never watered; the Grapes as a consequence were poor and unsatisfactory, so much so that the gardener relinquished his charge. A different system was then adopted. The concrete was broken up, and heavier soil incorporated with the border; heavy surface dressings of manure were given, and water copiously applied in the growing season; and the same Vines have since produced splendid crops of fruit, which are a source of pride of the owner as they are a credit to the gardener. Some of the finest Grapes that I have seen have been produced by borders which have been attended to by rich dressings of manure with occasionally fresh soil and bones at the top, rather than by a smooth layer of lime, tar, and ashes at the bottom.

Yet on the other hand I have known the concreting of Vine borders in conjunction with an effective system of drainage decidedly beneficial. Seven years ago a border site was excavated in a soil which approached clay. Drainage was put in—that is, a foot of stones, &c., and the soil made of a suitable compost, yet the Vines did not flourish. The berries shanked and did not colour well, and the foliage was much attacked by insects. The Vines were eventually lifted, and the soil was taken out. A layer of concrete was placed on the drainage, and drains made with sharp falls and clear outfalls; the border was enriched on the surface, and water given freely; and for the past two years the crops have been of the very first order of merit. In this case I doubt not that the manure at the top has been of greater benefit than the concrete at the bottom, yet the two in conjunction have proved the practice to have been correct and good.

I can quote another instance. A clergyman was most anxious to have good Grapes, but his border site was in a natural hollow and the soil was clay. An excavation was made and a good border compost put in, but the Grapes were not good. The natural hollow was simply a water trap, and a layer of concrete was placed on the surface of the border—previously taking up the Vines—another border being built entirely above the ground level, and the crops have since been most superior. This border is heavily top-dressed annually, and frequently watered with sewage until it passes through the mass of soil and out by the drains.

This record of practice may be useful at a time when Vine borders are in the course of construction and renovation. It tends to prove that concrete is useful where not abused. When it is necessary it should be laid with a sharp gradient and in connection with drains which must be kept in order. If the site is very low and the soil heavy and wet, it is advisable that the border be made entirely above the ground level. But in many, and I am inclined to think in most, instances concrete is not necessary, and of infinitely greater moment is

the enriching of the surface of the border, and keeping it moist in the season of growth. Vine roots are like sheep, they will not wander far from a good feeding-ground; but when the pasture is bare and affords them no support it is difficult to prevent them passing a prescribed boundary.—A NORTHERN GARDENER.

## ROYAL HORTICULTURAL SOCIETY.

DECEMBER 1ST.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. Mr. Jones, the Royal Gardens, Frogmore, sent three very handsome specimens of Smooth-leaved Cayenne Pines, each weighing about 8 lbs., which were awarded a cultural commendation. Messrs. W. Paul & Son, Waltham Cross, sent six dishes of Pears, consisting of Jewess, Comte de Flandres, Emile d'Hayat, Broom-park, Dr. Trousean, and Beurré Beauchamp. He also sent a seedling Pear without a name, which was of a good but not superior flavour. Messrs. Kinmont & Kidd, nurserymen, Canterbury, sent a seedling Apple from Court of Wick crossed with King of the Pippins, but its flavour was not distinct; a seedling from Devonshire Quarrenden, very similar to the parent, but the flavour was inferior; and Swinard's Seedling, also a seedling from Devonshire Quarrenden, which was not of remarkable flavour.

Four seedling Apples were received from Mr. Charles Arnold of Paris, Ontario, Canada. They were raised from Northern Spy crossed with mixed pollen of Wagner and Spitzberg. No. 1 was very acid. No. 2, a firm-fleshed and rather acid Apple. No. 3, tender flesh and slightly sweet, but not good. No. 5 is very tender-fleshed and sweet, but the Committee did not consider either of them worthy of a certificate. A letter of thanks was voted to Mr. Arnold for sending the fruit. Mr. J. Charlson of Tonbridge Wells sent a seedling Pear of a Bergamot shape, which had a powerful flavour of Gansel's Bergamot and very gritty flesh. It was thought that it might be better in another season. Thomas Laxton, Esq., of Stamford sent a seedling Apple called The Boy's Delight, a small striped Apple of very tender flesh and rather sweet flavour. Boothby's Seedling No. 4 is also a very tender-fleshed variety, which was thought to be a good cooking Apple. Boothby's Seedling No. 8, a medium-sized, oblate, yellow Apple of tender flesh and very briskly flavoured, and was thought to be a good Apple for sauce. The Doctor is also a medium-sized Apple but of no character. No. 7, a seedling from Cox's Orange Pippin fertilised by Stamford Pippin. No. 8, a seedling from New Hawthornden crossed with Stamford Pippin. No. 9, very disagreeable.

There were others, but they like the preceding were inferior to many others in cultivation. Mr. Trussler of Edmonton sent a small seedling Apple which did not possess any special merit.

**FLORAL COMMITTEE.**—Dr. Denny in the chair. Only a very few exhibits were brought before the Committee on this the last meeting of the season, the weather being altogether too cold for the safe transit of tender plants. No certificates were awarded—the numbers awarded at previous meetings during the year being ninety.

Mr. Clarke, florist, Twickenham, sent a hundred plants of Cyclamens, well-bloomed sturdy plants, with good-shaped flowers in a great variety of colours. Some of the dark colours—crimson, magenta, and purple—being very rich, and whites pure. This charming class of plants are evidently as valuable for winter as they are for spring decoration. Mr. Clark also exhibited a selection of eighteen Cyclamens of vigorous habit, and with exceptionally large flowers, but limited to the lighter colours. For these collections a vote of thanks was deservedly awarded.

Messrs. Waterer & Sons, The Nurseries, Bagshot, exhibited plants of *Thuja picea borealis aurea variegata*. The plants were small but of robust habit, and with their vigour a constant variegation of golden sprays. For this very promising ornamental lawn Conifer the thanks of the Committee were awarded.

Mr. Westcott, The Gardens, Baby Castle, Darlington, exhibited a new hybrid Solanum Princess of Wales, a cross between Prince of Wales and Yellow Gem. It is a highly ornamental variety, the pyriform fruits being of the brightest yellow, 2½ inches in length and an inch in diameter, the foliage being 5 inches in length by 4 in breadth. This vigorous hybrid is strikingly effective, and cannot fail to be useful as a winter decorative plant. A vote of thanks was awarded.

**IMPROVING THE FLAVOUR OF FRUIT.**—It is not a little surprising that those who would enjoy the full flavour of Apples and Pears do not pay more regard to the temperature of the fruit when placed on the table. Many, if not all, sorts of Pears are immensely improved by being subjected to a temperature of 100° for an hour or two previous to being eaten. To take the best kinds of fruit direct from the fruit-room, which may not be half a dozen degrees above the freezing point, is not doing justice to the fruit or, I must add, to the

owner. Let anyone test fruits of any good sort of Apples and Pears, some "stinging cold" and others artificially warmed, and note the superiority of the latter, which is to my mind conclusive.—A CITY MAN.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

**DELPHINIUM CASHMIRIANUM.** *Nat. ord., Ranunculaceae. Linn., Polyandria Trigynia.*—Flowers purple. "About a dozen species of Delphinium inhabit the Himalaya Mountains, of which the present is one of the handsomest. All are found at considerable elevations; and some of them that come from the loftiest spots, as *D. Brunonianum*, *Royle*, exhale so strong a musky odour that the ignorant mountaineers attribute the odorous secretion of the musk-deer to the animals' feeding on that plant, and of the *D. glaciale*, which is equally strongly scented. No such odour has been attributable to *D. Cashmirianum*, though it too occurs at great heights, ascending from 12,000 to 15,000 feet in the Western Himalaya, where it ranges from the longitude of Kumaon to that of Kashmir, abounding in grassy valleys, &c. The subject of this plate was raised by J. Anderson-Henry, Esq., from seed sent from the north part of Kashmir by Dr. Bellew during his journey to Kashgar with Mr. Forsyth, and it flowered well at Hay Lodge, Trinity, in July of the present year."—(*Bot. Mag.*, t. 6189.)

**MADEOVALIA DAVIESII.** *Nat. ord., Orchidaceae. Linn., Gynandria Monandria.*—Native of Peru. "This fine *Maedevalia* is remarkable for its size and colour (yellow). It was discovered by Mr. W. Davis near Cuzco in Peru, and was flowered by Messrs. Veitch in August of the present year; the plant here figured bearing twenty flowers. Singular as the colour is, it is probably very variable. Reichenbach describes the perianth-tube as 'whitish yellow, with a blackish-violet great eye-spot on each side;' and the other parts of the flower as 'yellowish-white outside and of the deepest splendid orange inside;' colours not at all repeated in our specimen."—(*Ibid.*, t. 6190.)

**TULIPA EICHLERI.** *Nat. ord., Liliaceae. Linn., Hexandria Monogynia.*—Flowers dark crimson. "It belongs to the group *Scabriscapae* of Baker, all the species of which are natives of the Mediterranean region, from Italy eastward to the Levant, and of the Caspian region extending to Turkestan. This, indeed, is the principal area inhabited by Tulipa, for very few of the species (nearly fifty are described), reach the extreme east of Asia; only one is found in India (*T. stellata*, Hook.), and that is confined to the North-eastern Himalayas, and one (*T. edulis*, Baker), in Japan. The *T. Eichleri* was discovered by the traveller whose name it bears, in the Baker district of Georgia."—(*Ibid.*, t. 6191.)

**HETERANTHERA LIMOSA.** *Nat. ord., Pontederiaceae. Linn., Triandria Monogynia.*—Flowers violet-blue. "A very pretty water-plant of wide distribution, inhabiting very wet marshes from Virginia to Venezuela and Brazil, and likely to become a favourite for cultivation in tropical aquaria, where it may be grown in pots standing in the water. As far as I am aware, but one species of the genus *Heteranthera* had hitherto been cultivated in Europe—namely, the *H. graminea* of Vahl, a very insignificant submerged species, a native of North America, which was introduced into the Glasgow Botanical Garden half a century ago along with *Vallisneria spiralis*, and is well figured in Hooker's 'Exotic Flora,' tab. 94, under the generic name of *Leptanthus*. About a dozen species of the genus are described, some of which, having spikes of blue flowers, are no doubt worthy of cultivation. Seeds of *H. limosa* were sent from Santa Martha, in New Grenada, to the Royal Gardens by M. Endres, which germinated and flowered in the short space of a few weeks. M. Endres states that it grew in brackish pools. It flowers at Kew from May onwards. It is a plant of very wide range, from the warm temperate region of the United States (Illinois and Virginia), to Bahia in Brazil."—(*Ibid.*, t. 6192.)

**OXALIS ARNICA.** *Nat. ord., Oxalidaceae. Linn., Decandria Pentagynia.*—Flowers purplish pink. "The genus *Oxalis*, once a favourite amongst amateur horticulturists, has of late years experienced the neglect that has overtaken so many interesting classes of herbaceous plants. Upwards of 180 species, chiefly natives of South Africa, have been figured as under cultivation in Europe. By far the larger number of these are contained in the beautiful Monograph of the genus published by the elder Jacquin in 1794, from specimens cultivated in the Imperial Gardens at Vienna. In 1808 fifty-eight species were in the Kew collection, where there are now only thirty; and no

species has been figured in this magazine for a quarter of a century, when (1850), the lovely *O. elegans* of the Andes appeared. Happily a love of the genus lingers amongst scientific horticulturists, to one of whom, G. Munby, Esq., I owe the opportunity of figuring the present species. *Oxalis arenaria* is a native of Chili, where it is widely distributed, being found in sandy pastures near Valparaiso, Santiago, and other localities. It has also been gathered on the Andes of Bolivia by Mandon, in the neighbourhood of Sorata, at an elevation of between 8000 and 9000 feet above the sea-level. The specimen here figured flowered with Mr. Munby in March."—(*Ibid.*, t. 6193.)

**CRASSULA BOLUSII.** *Nat. ord.*, Crassulaceae. *Linn.*, Pentandria Monogynia.—Flowers white and crimson. Native of South Africa. "It was discovered by Mr. H. Bolus, near Graafreinet, who sent both living and dried specimens to Kew. As a species it is closely allied to *C. Cooperi* ('Regel Gartenfl.', 1874, p. 36, t. 786), a widely distributed Cape species, but differs in the less straggling habit, much longer and narrower radical leaves, and in the dark blotches on the foliage. Plants were sent to Kew by Mr. Bolus in 1874, which flowered in the Succulent House in July of the present year."—(*Ibid.*, t. 6194.)

**APPLE**—*Lane's Prince Albert*.—"It is a variety which has been well proven in certain districts, and which well deserves to be more widely cultivated. It was raised some years since by Messrs. Lane & Son of Berkhamstead, from the Russet Nonpareil crossed with Dumelow's Seedling, and is remarkable both for its excellent quality as a culinary Apple and for its prodigious bearing qualities, even the smallest trees being usually densely laden with fruit. The fruit is large, shortly conical or ovate, in the larger samples 1½ inches in circumference, and measuring 6 inches from eye to stalk, even and regular in outline, with broad ribs round the crown. The skin is smooth, of a fine grass-green, covered with appreciable bloom, changing as it ripens to clear, pale, greenish-yellow, flushed on the exposed side with crimson-red, and also marked with short, deeper, crimson streaks. The eye is closed, with small, pointed, reflex segments, which are set in a deepish, somewhat angular basin. The stalk is about half an inch long, inserted in a deep funnel-shaped cavity. The flesh is tender, juicy, briskly and agreeably acid with a pleasant flavour. In this variety we have a culinary sort which can be safely recommended not only for its bearing and keeping qualities, but also for its general excellence, in respect to flavour and texture, regarded as a kitchen Apple. The fruits are heavy, and have a solid feel about them."—(*Florist and Pomologist*, 5 a., viii., 233.)

## SLAUGHTER OF SMALL BIRDS FOR LADIES' HATS.

IF on reading the enclosed extract you feel as indignant as we do, will you find space for it in the Journal? It is such a horrid fashion that everyone should do what they can to check it:—

"The fashion now so prevalent of ornamenting ladies' hats and bonnets with small birds has given such an impetus to the activity of the birdcatchers, both here and in France, as to cause well-grounded fears for the annihilation of our favourite little songsters. This was forcibly pointed out in a case which came before the Dover Bench yesterday, in which two men were charged with trespass. Upon them were found no less than fifty-one dead skylarks and a large number of linnets, thrushes, bullfinches, &c. A gentleman connected with the Customs at Dover stated that it was well known that a large premium was paid to men like the prisoners for these birds, and that it was within his cognisance that during the past fortnight no less than two thousand of the brightest-plumage birds from Normandy passed through Dover on their way to a firm of milliners in London, their destination evidently being to ornament the hats and bonnets of Belgravian ladies. The Bench stated their determination to punish severely all future offenders, and ordered their clerk to make a representation on the subject to the Home Secretary.

"We must try and stop the demand. We must grapple with the cause of the evil, which is to be traced to the present fashion of affixing the bodies of skylarks, thrushes, linnets, &c., to ladies' hats by way of ornament—a fashion which is inartistic, unclassical, and vulgar, and which displays a vitiated taste."—M. G.

[No words would be too strong to condemn the fashion

held up to scorn by the writer of the above letter. The fashion is one of those masculine changes condemned by good taste. We have noticed in country towns, as well as in London, that birds are worn by those who at other times wear in their hats huge flowers, bunches of Grapes, and clusters of Cherries, all of the largest size and deepest colours. All this is most vulgar, yet we should not feel that such error is within our province to condemn; but the slaughter of small birds justifies us in remonstrating and asking our readers to aid in suppressing it. Those small birds are some of the gardeners' and farmers' best friends. The goldfinch, the linnet, the hedge sparrow, the lark, and others live upon the seeds of weeds and insects, and of all of them we have seen hundreds of skins lying in the windows of ladies' hat-makers. Let every head of a family forbid their use, and let every girl adopt exclusively that utterance of true taste—

"Flowers and ribbons small and fair,  
Are round my hat and in my hair."

—EDS.]

## NOVELTIES IN THE ROYAL GARDENS, KEW.

FLOWERING in the Succulent house at the cold end we find a member of the elegant genus *Bomarea*, which, with a query attached, is named *B. Jacquesiana*. It resembles in some degree the very handsome *B. chontalensis*, introduced about four years ago by Mr. Wm. Bull, having similar rose-coloured outer segments with a few black spots. It is, however, quite distinct, the flower being almost half as long again and of less globular outline. The leaves of this are very bold and fine-looking—far more so than those of *B. Caldasii*, of which there is a plant on the opposite side of the door. They are growing against the end of the house, and form a good covering for the glass, which without some kind of greenery would look painfully bare. Both are planted out, and do remarkably well with but trifling attention. The *Bomareas* are rare in cultivation, although they are pretty well known as handsome twiners. One species, *B. edulis* of St. Domingo, supplies the *Tapinambours blancs*: these are the tuberous ends of the roots, which after being boiled are eaten as Potatoes.

In this house a plant of the *Clivia Gardenii* is beautifully in flower, and coming in regularly at this season it seems to be worth attention. The leaves are much like *Imantophyllum* minimum, to which it is nearly allied, but with flowers more like *Cyrtanthus*. They are produced in large umbels, and are of an orange-red colour with green tips. The cultivation for *Imantophyllum* suits it exactly. *Aloe ciliaris* deserves a passing notice. It is a slender-growing species, which may be trained as a climber. Spikes of flowers come on every branch; they are not too large, and having the fiery colour of *Tritoma* at once strike the attention. It is the most brilliant-flowered of all the Aloes.

*Olea fragrans* is flowering in the Economic house, and possesses a perfume of the most delicious description. The flowers are small and of a pale yellow colour, but grow many together in numerous clusters. They are used in China for scenting teas. That called *pekoe* is a green tea much prized for the scent imparted to it by these flowers. The species is well worth growing in conservatories for its perfume. It is easily grown and succeeds on its own roots, but is perhaps harder grafted on Privet. A plant so grafted has withstood the last two or three winters against a wall.

In the Orchid house we find a good pan of *Pleione laganaria*, perhaps the most beautiful of the Indian *Orocucos*. About twenty flowers are fully expanded. *P. maculata* is also in bloom. *Cirrhopetalum Medusae* is extremely curious, and of similar character it would be difficult to find anything else. The flowers are numerous on short spikes, and the sepals are lengthened into long threads, hanging down like coarse hair. *Pachystoma Wightii* is a pretty plant from India. The leaves are grassy, accompanied in this case by a single yellow flower the size of a Primrose, borne on a stem about a foot high. We have before drawn attention to *Eulophia guineensis*; it is again in flower, and without doubt is a valuable terrestrial Orchid, the flowers lasting long in perfection, and being of distinct colour and form. They are produced on erect stems about 2 feet in height. It is a native of West Tropical Africa, and requires warm treatment. Among *Cypripediums* are *C. Stonei*, the rare *C. pardinum*, *C. concolor*, *C. Boissii*, *C. Sedeni*, and of the commoner *C. insignis* some good masses are well in flower. *Angracum pellucidum* is always attractive from its beautiful glossy foliage. Its beauty is now further

enhanced by many pendulous spikes about a foot long, bearing a large number of white translucent flowers. It is well adapted for growing in baskets. A yellow-flowered form, more rare than this, is sometimes met with.

### NOTES AND GLEANINGS.

THE OXFORD BOTANIC GARDEN we do not consider too small if it were differently arranged. Certainly it would do violence to the feelings of everyone who knows its history to have it abolished and another established elsewhere. Such a change is not needed.

— We regret to have to announce the DEATH OF M. ALPHONSE MAS of Bourg-en-Bresse, at the age of fifty-nine. M. Mas devoted almost the whole of his life to the study of pomology. In his garden at Bourg were collected almost every variety of hardy fruits he could procure, and there he made his observations which formed the groundwork of *Le Verger*. We are especially saddened at the occurrence of this event. It was only in September last that the writer of this met his old friend at the meeting of the Société Pomologique of France, which was held this year at Ghent, and where he as President of the Society performed all the duties of his office. M. Mas was a man of gentle and amiable disposition and a sincere friend, and his loss will be much regretted by a large circle, among whom he was well known and esteemed.

— THE FLOWER MISSION has been very successful among the patients of the metropolitan hospitals and the poor in the east of London. It is worked from depôts where the flowers are sent, and they are arranged in neat little bouquet-holders of paper, with a text of Scripture written on them, and distributed in hospitals, workhouses, and to the sick poor in their homes. Two central depôts were opened in March at Mildmay Park and Spitalfields, and in the flower season the average number of bouquets sent out from them was from 8000 to 4000. The movement has attracted much attention among ladies, and no doubt its action will be widely spread when the spring flowers come in. In support of the funds of this Mission a bazaar, under the patronage of the Duchess of Cambridge and the Duchess of Teck, was opened at the Hall, Gloucester Road, Kew, and attracted a large number of visitors.

— At the Birmingham Cattle Show Messrs. Carter & Co. have a stand of AGRICULTURAL AND HORTICULTURAL PRODUCTS, all very fine, grown from seed raised by them and contributed by the growers. Among the horticultural specimens there are some extraordinary Carrots, Parsnips, Potatoes, &c., in endless variety and of the finest shapes and quality. Onions, too, are in abundance, and the form and size of some of them would have astonished gardeners of no very remote period.

### HEATING WITH PEAT.

In answer to your correspondent "W. W." (page 482), I may state that my experience of peat or turf for heating hot-water boilers has been very unsatisfactory. Of course much depends on the quality; spongy turf cut from the surface of the bog is all but useless except wood or coke is used with it, and even then I have found a great difficulty in keeping up a regular temperature in frosty weather. There is a hard black peat, generally the lower spits of a turf bank, and where all vegetable matter has been long decomposed, which suits much better, and for a small house might maintain a pretty fair temperature without much trouble.—A. MCINTOSH, *Gortmore*.

### OUR BORDER FLOWERS—SISYRINCHIUMS.

THESE are hardy and half-hardy plants of great beauty, and are well adapted for spring-garden and border culture. They are widely distributed, and are found in many parts of the world. The hardy kinds stand through our winters without injury. They succeed well in a well-drained situation, extreme moisture being fatal to their well-doing. If the soil is of a strong heavy nature it should be removed altogether, and be replaced with the following compost—good sandy loam and sandy peat in equal quantities, with a little well-decomposed leaf mould and a sprinkling of charcoal dust and sand mixed well together. The soil should be made a little firm before planting. The plants are easily increased by division of the roots after they have matured their growth. The half-hardy

kinds must be protected through the winter in a dry cold pit or greenhouse where they can be kept from frost, and they may be planted out in the summer, but should be taken in before the frosts set in. Their splendid diversity of colour and graceful habit well repays any labour bestowed upon them.

Among the hardy kinds none are more beautiful than *Sisyrinchium grandiflorum*, its colour being crimson purple. It is an early bloomer and grows about a foot high, and when well established it produces a charming effect. *S. grandiflorum album* is equally attractive, its lovely white blooms contrasted with the foregoing being beautiful indeed. *S. striatum* is one of the tallest of the family, not so bright in colour as some of the species, but is still a very desirable border plant and continues long in flower. *S. convolutum* is one of the handsomest of the whole family; when well established its large yellow flowers tell us at once that it is worthy to stand high in our estimation; it should be in all collections of herbaceous plants. *S. odoratissimum* should have a place on account of its delicious perfume; it is of dwarf habit and is rather tender, and should be protected through the winter. *S. aniceps* is the commonest and the dwarfest of the tribe. I have seen it very beautiful in early spring used as an edging plant. It soon establishes itself, for it seeds freely and in some places becomes troublesome as a weed.

I have sometimes known the early blooms destroyed by our spring frosts, which should be guarded against in our unsettled climate. A few hoops of small wire made with prongs to run into the ground in the form of a bee hive covered with coarse canvas is a good protection for these plants, and the covers are easily removed when not required. It is not my intention to enumerate the family, or I might name many more kinds worthy of the cultivator's notice.—VERITAS.

CARTER'S GREEN GAGE TOMATO.—I have this season grown the above Tomato along with three others, and I find it quite an acquisition. The other three varieties were Large Red, Excelsior, and Arlington. It ripens under the same treatment quite as early as Large Red, and those who have tasted it here consider it superior in flavour to that variety. I likewise consider it more productive than either of the other varieties, although the fruit is smaller. These notes refer to the culture in pots and grown under glass. I have it planted out along with the other varieties, but the season has been so unfavourable for outdoor Tomatoes that I cannot speak decidedly on its merits outdoors.—J. ANDERSON, *Hill Grove, Kidderminster*.

### PLANTS FOR CUT FLOWERS AND SPRAYS.

No. 7.

ALLIUM.—This is a genus of very valuable plants. *A. fragrans*, white striped with green, is delightfully fragrant. *A. magnum*, white, is also sweet-scented. They flower during June, and are quite hardy, doing well in ordinary soil, but best in sandy loam enriched with leaf soil and well drained, planting the bulbs about 8 inches deep. The flowers keep well in water, continuing a long time in bloom. *A. ellatum*, white, and *A. azureum*, blue, are very pretty; *A. moly*, canary yellow, is also very free and fine; *A. triquetrum*, white, drooping, is very desirable and earlier than most of the species. These showy plants ought to have a place in every garden.

SCHIZOSTYLIS COCCINEA.—This is a *Gladiolus*-like plant, and has deep scarlet flowers. I had plants this season with flowers in July; the plants were moved to a greenhouse in the middle of October, and will flower as in previous years—all through the winter. It is, however, quite hardy, but if its flowers are wanted in winter a light airy position in a greenhouse must be given. The plants are placed outdoors in May, potted in June, and duly supplied with water. They flourish best if under rather than over-potted. Good turfy loam three parts and one part of leaf soil is a suitable compost, but I add a little peat and silver sand, finding that all *Irids* are improved by peat. For growing outdoors a sheltered position is desirable, and a sandy well-drained soil. It ought to be grown by everyone wishing flowers to cut in late summer and autumn, also during the winter in a greenhouse.

ORNITHOGALUM.—These flower in spring or early summer, and are useful; they are best treated as cool greenhouse plants. *O. thyrsoides*, yellow; *O. arabicum*, white with dark centre, and sweet; and *O. Bergii*, white and green, will be suffi-

cient for pots. *O. pyramidale* and *O. umbellatum* are suitable for borders. Light fibrous loam, with the compost named for *Schizostylis*, will be suitable for *Ornithogalums*. Free watering during growth is necessary, keeping the soil just moist when the plants are at rest.

**LEUCOCORUM.**—*L. vernum*, which blooms in spring (March) has the scent of a Wallflower, and is very beautiful from its pearly whiteness and tips of clear yellowish green. *L. astivum* is also white tipped with green, and flowers in June or earlier. *L. autumnalis* has bell-shaped flowers, white tinted with rose, and flowers in September. Like monster Snowdrops the Snow-flakes are very valuable for cutting from, and should be grown extensively. They will grow freely in any ordinary garden soil, and delight in moisture. Plant 3 inches deep in an open situation.

**ERYTHRONIUMS.**—These have very beautifully-spotted leaves, which are useful and force readily; the flowers are also useful, and come-in in March or April. These plants will grow almost anywhere, doing best, however, in light loamy soil with leaf soil and peat.

**GRIFFINIAS.**—*G. Blumenavia* has delicate rose-striped flowers, and *G. hyacinthina* has white flowers striped with sky blue. Than these there are no finer autumn-flowering *Amaryllids*, having large clusters of beautiful large Lily-like drooping flowers, produced successively for from six to ten weeks. They are stove plants which ought to be extensively grown. The plants require a light position throughout the year, and should be potted in spring. They should be copiously watered during growth, and not at any time the leaves allowed to flag, for they are evergreen, and the plants ought never to be dried-off so as to lose the foliage.

**AGAPANTHUS UMBELLATUS.**—This is a fine old plant, and with *A. umbellatus albus* flowers in spring (April) in a greenhouse, and if the plants are wintered in a cool house and subsequently placed outdoors they flower in August. The flowers are very useful for cutting purposes. Water very freely during growth, and keep dry in winter, but let it be that sort of dryness which will keep the foliage fresh, for they are evergreens. Pot in spring or after flowering. Three parts fibrous loam, and a part each leaf soil and fibrous peat, will grow them well.

**ANTHOLYZA ÆTHIOPICA** is a desirable plant, and requires the same treatment as *Schizostylis*.

**TRITELMIA UNIFLORA** is also useful for affording cut flowers, and is as easily cultivated as the *Crocus*.

**TRILLIUM GRANDIFLORUM** (Wood Lily) is a fine plant for moist ground, and if potted in the autumn and brought forward in gentle heat flowers early in spring, and is beautiful.

**POLLANTHES TUBEROSA** (Tuberose).—This well-known favourite produces its flowers in tall spikes, and having soft stems they are good for cutting, for the buds will open successively to the last, whilst for bouquets, or the hair, every pip is available. The single variety may be said to have gone out of cultivation, but it will make its appearance occasionally amongst the Double White Italians. These are good, but the Americans are decidedly more vigorous and more floriferous, and are in every way superior. The variety, if I mistake not of American origin, named The Pearl, is of dwarf habit, not growing more than two-thirds the height of the old sorts; it has also finer flowers, and when it is more moderate in price it will drive its taller brethren out of the field. The tubers are not to be had until December, and an early bloom being desired they should be potted at once, removing the offsets and taking out all the buds except the central one, and then pot them in 6-inch pots moderately drained, and covering the tuber with soil, leaving only the apex clear of it, surrounding the tubers with silver sand, using a compost of light fibrous loam three parts, one part each of leaf soil, old cow dung or well-rotted manure, and silver sand well mixed. The pots may then be plunged in a hotbed of 70° to 75°. The top heat for at least a month ought not to exceed 65° by artificial means, nor should it be less than 50°. No water should be given until the foliage appears, and then commence to bring the soil into a moist state by watering around the inside of the pot; the top heat after this must be maintained at 60° to 65° at night, and 70° to 75° by day, with the usual fluctuation of 10° to 15° or more with sun heat, giving abundance of air. When the plants have made a good start they should be gradually withdrawn from the hotbed, or its heat should be allowed to decline, so that the plants will not receive a sudden check. In any light airy house with the temperature above-named they will, if placed near the glass, succeed admirably. The plants ought—when the pots are filled with roots, and before they are curled and

twisted into a mat—to be shifted into 7 or 8-inch pots, watering moderately for a time, and when the pots are filled with roots water twice a-week with weak liquid manure. Syringe the plants two or three times a-day to prevent the appearance of red spider, and if the syringing be not enough take two sponges wet with a solution of soft soap 2 ozs. to the gallon, and one in each hand commence at the base of each leaf and draw upwards, the leaf being between the sponges. A batch should be started every three weeks up to April; the first will flower in May, and some of the latter being placed in a greenhouse when in good foliage after being started in heat they will flower in August if warm, or September if cool, whilst the others of the April batch will, grown in heat, bloom late in July or early in August, and a later lot potted in April but not started until May, and when growth commences forwarding in a greenhouse will produce blooms in October. In all cases I prefer to pot in a moderate-sized pot, and to shift, before the stem rises, into pots that will admit of at least 1 or 1½ inch of fresh compost all around, draining well at the last potting, as the watering must be copious—not soddening, nor on the other hand allowing the foliage to flag.

**EUCHARIS AMAZONICA.**—This is essentially a lady's flower, both for hair and dress, combining purity of colour with delicate fragrance. Some can scarcely command a bloom of this plant at all, others flower their plants twice a-year, and some four times, which means never-out-of-bloom. Some force them into flower with bottom heat, and others starve them—that is, they rest them in a pit or greenhouse, and flower them in a stove. When there is such a diversity of opinion how is anyone to decide correctly?

There are at least two if not more varieties of *E. amazonica*, or the species are confounded. There is a kind which commences growing in December or January, and this has very much stouter petioles and very much shorter, with considerably broader and thicker leaves, deeper in colour, and has larger heads of bloom, and more numerous blooms than a variety which commences growing or flowering in May, and which is remarkable for its long leaf petioles, its thinner-textured, smaller and paler-coloured leaves, and smaller flowers with a paucity of them. Is not the former *E. grandiflora* syn. *amazonica*, and the other *E. candida*? I think so.

In January the bulbs are to be shook-out of the soil or the soil removed, and four or five of the largest potted in a 10 or 11-inch pot, and draining well, using a compost of three parts turfy loam and one part each of well-rotted cow dung and fibrous peat, and pot so as to just cover the bulbs. Three bulbs may also be placed in an 8 or 9-inch, and one in a 6 or 7-inch pot. Place in a warm stove 60° to 65° at night, 70° to 75° by day, and keep very moist, and in March or April they should flower, and for blooming they may be placed in a cooler house, and afterwards be returned to the stove, when the plants not unfrequently flower again in July. It is better, however, to rest the plants for a time after flowering, say six or eight weeks, in a cool stove or a cold pit after May, which by judicious air-giving is a stove, watering only to prevent the leaves flagging, and introducing to heat again, when the plants will flower in August or September. Plants may be had in bloom at almost any time by growing them in brick heat and affording abundant air-moisture and water, and when the growth ceases rest them near the glass in a warm greenhouse (55°–50° min.) with water only to keep the foliage from flagging, and with a syringing overhead once a-day they will scarcely need water until required for starting. The rest should not be less than six weeks. Another mode of culture is not to dry the plants at all, but after flowering, or when the growth is complete, to place them in a house of about 10° less heat than that in which they are grown, but light and airy and by no means so dry as to affect the foliage, and with ten weeks of this cool treatment to return them to heat, giving plenty of it, for they enjoy strong moist heat and liberal watering during growth, and after flowering and completion of growth rest in a cooler house.—G. ABBEY.

### TOPIARY WORK.

On page 229 we inserted notes and an illustration of the topiary work for ornament at Elvaston Castle, and we now add another example of the useful topiary work at the same residence—in other words, of the clipped evergreen hedges in its garden.

No one who has not tried the experiment by the aid of a thermometer can duly estimate the superior protection afforded

by an evergreen hedge compared with that afforded by a deciduous hedge. We have repeatedly found on the leeward side of a Laurel hedge, and of a Yew hedge, the thermometer showed 10° of higher temperature than on the leeward side of a Blackthorn hedge, and a Hawthorn hedge. A Holly hedge would probably be as good a preventive of cold, but we have not had an opportunity to test it.

If the evergreen hedges are curved as at Elvaston they are more sheltering from winds, and consequently more preservative of temperature, than if in straight lines. Such hedges should not be less than 2 feet thick and 5 feet high.

Hedges as mediums of shelter might in exposed districts be more advantageously employed than is the case at present. Many are the gardens, especially those recently made, which are quite destitute of provision against high and cold winds, and also—for this is important—against the overpowering

effect of the sun in summer. None, except those having the management of gardens entirely exposed, can appreciate how earnest and, too often, how hopeless is the longing for a shaded "north border." A garden without this necessary adjunct, and, of course, its corollary the "warm" south border, is incomplete, as lacking the invaluable means of accelerating and retarding many important crops. Where walls are not provided (in many places they are inadmissible), a great use may and ought to be made of evergreen hedges.

Their utility and value is appreciated in nurseries where they are employed to a much greater extent than in private gardens, and we may be assured that this would not be unless they answered important protective purposes against cold on the one hand and heat on the other. This is, perhaps, even more apparent in continental than in English nurseries.

There can be no doubt whatever that to judiciously interest

Fig. 106.—TOPIARY WORK AT ELVASTON CASTLE.

exposed gardens with neatly-kept evergreen hedges would be to increase the usefulness and profit of the ground to a very considerable extent, and at the same time would add to the appearance of such unbroken flats, and render the gardens more diversified and attractive.

We have frequently been envied the aid of a fine Yew hedge running east and west with its sloping warm border on the south side, and still more so perhaps the cool border on the north. As a space in which to plunge pot plants in summer a shaded border is indispensable, and not in a less degree is it valuable for purposes of propagation. A hedge will afford all that is necessary for shelter and shade, and would also be ornamental where a wall would be totally out of place.

Frame and forcing grounds should invariably be protected by walls or hedges. The consumption—really waste—of heating material in forcing *Seakale* and *Rhubarb* is enormous when the site is exposed; while on the southern side of a thick hedge the work is easy, and the shelter is almost worth half the manure.

In connection with this subject may also be mentioned the formation of the ground. In making new garden a great expenditure of labour is frequently indulged in in levelling the ground—that is, the ground for the kitchen garden, when the very undulations which are removed at such great expense might by judicious treatment be made of the greatest value. We

are intimately acquainted with a garden which is simply a series of hills and dales; and on the ridges, following their conformation, are neat Yew hedges, the borders sloping to the walks and facing almost every point of the compass. In this garden there is no wall, yet the district does not produce earlier and better Peas and Potatoes, and afterwards Cucumbers and Vegetable Marrows, than come from its sheltered borders; and on the shady slopes salads and Strawberries are prolonged to a period when they could not be had on perfectly level ground. To dig up the hedges and level the undulations of that garden would be to rob it at the same time of a great measure of its usefulness as well as its attractive features.

As the results of much experience and observation we are convinced that the usefulness of evergreen hedges as aids to the gardener are not fully appreciated, and there are thousands of bleak gardens that would be greatly improved by such divisional evergreen lines tastefully disposed. But we know what is the great bugbear—their impoverishment of the soil. Yet this is not so formidable as it seems. When once a hedge has attained the desired size regular clippings prevent it making much growth afterwards, and when the top growth is restricted so also is the extension of the roots; and the support that such a hedge requires is really very little, and it is much more than compensated for by the assistance it affords to the crops in spring, summer, and winter.

Yew, Holly, Laurels, Arbor-Vitæ, Evergreen Oak, Phillyrea, &c., are all adapted for screens, but the Yew is perhaps the most tractable, the easiest kept in order, and long-lasting. The engraving affords a striking example of what may be effected with hedges as a means of affording shelter, and presents an idea that may be carried out in any mode that may be required where similar screens are needed, and where walls are not provided or would be inappropriate.

### THE NUTMEG.

Of immense commercial importance is the Nutmeg tree, *Myristica moschata*, syn. *M. aromatica*. It is also ornamental by its clusters of berries or fruit. The plant is not commonly met with in this country, and it is seldom grown except in botanical or official collections. Its cultivation, however, is not difficult. It thrives in a sandy loam and brisk heat, and cuttings strike freely inserted in sand and placed in heat under a bellglass.

Of the Nutmeg tree Dr. Hogg has written as follows in his "Vegetable Kingdom":—"It is a native of the Moluccas and neighbouring islands, but is now cultivated in Java, Sumatra, Penang, the Isle of Bourbon, Mauritius, and other parts of the East, and in Cayenne, Martinique, and some of the West India islands. It attains the height of 30 feet, with a straight stem and a branching head. The leaves are oblong-oval, glossy on the upper surface and whitish beneath, and with an aromatic taste. The flowers are male and female on different trees, insignificant, and of a yellowish colour. The fruit is round or oval, about the size of a small Peach, with a smooth surface, green at first, but becoming yellow when ripe. The external covering, which may be called a husk, is thick and fleshy containing an acrid stringy juice; becoming dry by maturity, it opens in two valves, and discovers the nut covered with its aril, or mace, which is of a beautiful blood-red colour; beneath the mace is a brown shining shell containing the kernel or Nutmeg."

"A plantation of Nutmeg trees is always made from seed, and it is not till the eighth or ninth year that the trees produce flowers. The sexes being on different trees, after the plants are two years old they are all headed down and grafted with scions taken from the female tree, reserving only one male stock for fecundation. The natives of the Moluccas gather the fruit by hand, strip off and reject the pulpy husk, detach the mace carefully, and expose it to the sun, which soon changes its beautiful blood-red colour to a light brown; it is then sprinkled with sea water to render it flexible and preserve it. The nuts are first sun-dried and then smoked, until the kernels rattle against the shell. This shell being removed, the kernels are dipped twice or thrice in lime water, laid in heaps for two or three days, wiped, and packed in bales or barrels. The unripe fruit of the Nutmeg is frequently preserved in sugar in the East; and before doing so it is necessary to deprive it of its acrid properties by soaking it in spirits."

HAVE any of your readers noticed the beautiful tints in the foliage of the Alicante Vine? It is a sight to behold the jet

black bunches hanging beneath a canopy of foliage striped and mottled with the deepest crimson. In an ordinary way the leaves change to a golden yellow colour. Can the unusual colour be in consequence of the heavy rains, or through some chemical action of the soil?—A. W.

### A VISIT TO GARSTON.

HAVING had for a long time a desire to see Garston, an opportunity offered itself in the month of August. We left the Exchange, Liverpool, by omnibus for Garston, which we reached after an hour's pleasant ride. The route was by Sefton New Park; having secured an outside seat we were enabled to

note objects by the way. Sefton New Park has been recently formed by the Corporation of Liverpool. It is tastefully laid-out, and trees and shrubs are growing freely. It contains a good sheet of water, and by a judicious formation of the grounds, rockwork and waterfalls are introduced at suitable points. We next pass through Aigburth Vale, a richly wooded valley, the eye occasionally catching a glimpse of some gentleman's mansion and grounds lighted up with bright flowers. The destination of the omnibus was near four cross roads, and we were somewhat puzzled, not knowing which turn to take, there being no trustworthy butcher's boy at hand. However, by turning to the right over the railway bridge we saw the Vineyard on the left.

Garston is not new to fame, but for some years past has been a noted place for Grape-growing, the name of Meredith being familiar to many readers; but some months ago this great Grape-growing establishment changed hands, and has now become the property of the Cowan-Patent's Company. Their system of heating is simply a miniature lime kiln

Fig. 106.—MYRISTICA AROMATICA.

with hot-water apparatus combined, the hot-water apparatus being built in the upper part of the lime kiln, so that the heat from the burning of the lime also heats the hot-water apparatus. It appears that the old saddle form of boiler seems well adapted for the purpose. At the time of our visit to Garston this new system of heating horticultural buildings was being rapidly pushed on by connecting the whole of the extensive vinerias and other houses; preparations were also being made for the manufacture of gas for the lighting of the establishment. The working-out of the system at Garston is on an extensive scale, and when complete promises to be a great centre of attraction. The whole of the extensive glass structures are to be heated on the lime-kiln principle. The old boilers which have done duty for heating the different ranges are for the present to remain where they are, but connected with the main system, yet shut-off by valves, so that in case of any accident to the kilns these boilers can be made to do duty independent of each other. This new system of heating is said to be satisfactory wherever it has been carried out, and the Company have received many flattering testimonials in favour of the system. We are told that these kilns only require attendance in feeding once in ten or twelve hours, so that the labour of stoking is reduced to a minimum, and night labour abolished. This will be a great boon to under-gardeners and others who have such duties to attend to. Those who have been in the

habit of seeing the ordinary lime kiln at work may, perhaps, fancy that large volumes of smoke will issue from the top of these kilns, but this is not the case, for the top is all cased-in like an ordinary hot-water apparatus, and the smoke carried away in fines and ultimately discharged from a tall chimney. I have a balance-sheet before me sent to the Chairman of the Cowan-Patent's Company by the Earl of Cawdor, where the system has been tried for twelve months, showing that the heating has been efficiently carried out, and a balance of £10 4s. 4d. is shown in favour of the system. I have since my visit been informed that the heating at Garston is in full working order, and that there has recently been a gathering to inspect the working of the new system.

In order to show the heating power required for this establishment I will here give the dimensions of the glass structures. No. 1, span-roofed house, 200 feet long by 42 wide. This house is divided, one-half being devoted to growing pot Vines, the other half for Pines. No. 2, span Camellia house, 144 by 26 with a winding walk through the centre. This may be called a sort of winter garden, Maréchal Niel Roses being trained up the roof after the fashion of Vines. No. 3, span, 144 by 26 (Muscat Grapes). No. 4, span, 42 by 21 (stove). No. 5, lean-to, 86 by 10 (nursery stock). The above are laid to one kiln apparatus, heating 5800 feet of 4-inch piping. No. 6, span, 65 by 24 (Muscat Grapes). No. 7, lean-to, 55 feet by 16 (vinery). This house is planted with Gros Guillaume, one Vine only planted and grown on the extension system. This was a sight well worth seeing, showing that the system is well suited to that fine Grape, which had good foliage, good bunches, and good berries, showing that Garston still maintains its high reputation as a Grape-growing establishment. No. 8, lean-to, 25 feet by 11 (fernery). No. 9, span, 64 by 23 (early vinery). No. 10, ditto, 55 by 31 (show house). No. 11, four ditto pits, average 48 feet by 12 (nursery stock). No. 12, pit, 49 feet by 6 (nursery stock). The above are laid to the kiln which also makes the gas for the establishment. This kiln heats 4000 feet of 4-inch piping. No. 13, span, 28 feet by 23 (Cucumbers and Tomatoes). No. 14, lean-to, 37 feet by 16 (vinery). No. 15, ditto, 142 feet by 15 (ditto). No. 16, lean-to, 116 feet by 19, north aspect. This house is planted with late-keeping Grapes, such as Lady Downe's, Gros Guillaume, &c. They were just colouring, but the latter looking very unhappy, and certainly out of its element in a late house with a north aspect. No. 17, two span houses, 62 feet by 13 (Vine eyes planted out). No. 18, ditto, 57 feet by 17 (stove). No. 19, two span pits, 57 feet by 10 (propagating). No. 20, ditto ditto houses, 62 feet by 13 (stoves). No. 21, span, 78 feet by 11 (fernery). No. 22, lean-to, 38 feet by 16 (vinery), Madresfield Court Muscat. This, like the Gros Guillaume, is grown on the extension system. This fine Grape, both in bunch and berry, was remarkably good, being well finished, the berries being as black as sloes and carrying a beautiful bloom. It seems a pity that this fine Grape is not a late keeper. The above are laid to one kiln, and heating 5800 feet of 4-inch piping.

All the kilns are connected by mains, so that one only or all may be set in operation as may be required, the whole combined power being equal to heating 20,000 feet of 4-inch piping. The kiln which heats 4000 feet of 4-inch piping also makes sufficient gas for two hundred burners. All the kilns are said to be doing their work well, and as the time is yet young in working out the system, the Company have not yet been able to strike a balance-sheet, but sanguine hopes are entertained that the undertaking will ultimately prove a success.

Garston is about six miles from Liverpool, and can be reached by rail from the central station.—G. R. ALLIS.

## NOTES ON VILLA AND SUBURBAN GARDENING.

THE cold pit or frame to the amateur is quite as important as a convenience for storing plants as it is to the general gardener. These structures are often the only means whereby a few plants can be secured or others raised for the supply of the garden during summer. Let us, therefore, look at some of the principal points to be attended to in order to save a few plants over the winter. If there is a greenhouse it should be stocked with the tenderest plants or any plants of doubtful health. The pit or frame should be filled with such as are a few degrees hardier. In many nursery gardens a great portion of the stock of Heaths, Azaleas, Hydrangeas, Myrtles, Fuchsias, &c., are preserved in brick pits the whole of the winter. The principal management consists in carefully covering them at nights and during frosty days, and carefully ventilating them in fine weather. There

must be no mistake about this matter; the object should be to try and have the foliage dry over every day if possible, and keep everything about the plants clean; all dead leaves to be kept cleared away, and the matter of watering be carefully performed.

Among bedding plants particularly the utmost care is needed. They should be examined every day if the weather will allow, because it might happen that a period of frost or bad weather might seal the plants against examination for several days, or even weeks, together, and it is important that this contingency be provided for. If not clean and clear of decay before being closed tender plants would damp-off, such as variegated Geraniums for instance. I have more than once been called upon to give an opinion as to the cause of bedding plants going off, and when I have visited the frame the plants have been almost covered with dead leaves in a rotten state; this is sufficient to cause the death of almost any succulent kind of plant.

The frames should stand in the driest spot to be found and on a bottom well drained, and the pots if not placed on a stage clear from the ground should at least be placed on a layer of dry ashes. Pits built of bricks with their walls tolerably thick, and covered with lights of the best glass well put in, will keep out several degrees of frost if covered up with mats. But during severe frost it is safest to protect the sides of the pit or frame with litter of some kind; or, as is done in nurseries, their sides are banked up with rotten dung and other rubbish. This work is done about this time of the year and cleared away in the spring after all danger from frost is over, and seldom, if ever, does the frost penetrate through the whole. By a constant system of covering up the glass becomes dirty; this must be washed occasionally in order to afford the plants the most light possible during the dull winter months.

Whenever the plants are cleaned let each pot be taken out and the soil stirred up on the surface, and if wet apply a little dry silver sand, and even if thrown over the foliage it will absorb the moisture and assist to dry both soil and plants. Turn the plants frequently, and at times examine the drainage to see that nothing is in the way to prevent the free escape of the water.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

WHEN but little else can be done in consequence of unfavourable weather, manure and vegetable-mould heaps may be turned over. Where farmyard manure cannot be obtained in sufficient quantity for the use of the garden, a heap where all the trimmings of vegetables, plants from the flower garden when they have served their purpose, Hollyhock and Dahlia stalks—indeed, all succulent vegetable matter thrown together, is a *sine qua non*. Of course such a heap must be at a sufficient distance from any dwelling-house, as the smell from it is offensive. When the material has sufficiently decayed it may be dug into the ground the same as manure, and it is well adapted for any crops. We knew a gardener who used to grow most excellent crops of vegetables, and his main supply of them used to be grown entirely by the aid of manure from the vegetable-mould heap. Not a leaf of any kind was wasted, and the young gardeners were sent as time could be spared to gather leaves in the park. It was no part of the gardener's duty to collect the leaves, but their value as manure was an ample equivalent for the labour of collecting them. In the course of a season an immense heap was formed, half of it being composed of the sweepings from the park. The drainage of the farmyard, which in many places is allowed to run to waste, was collected in a large tank, and as occasion offered a quantity of it was carted to the place and thrown over the heap. Now here was a large garden of four or five acres kept in good condition by double-digging and trenching, and almost without the aid of farmyard manure, as the spent Mushroom and Melon beds were required for the use of the flower garden almost exclusively. If a gentleman takes any interest in his garden he will not allow his gardener to be put to such shifts; on the other hand, when but little interest is taken in the garden by the owner, the gardener still wishes to do all he can in the way of keeping up a supply for his own credit. We pay considerable attention to all crops of salads and Cauliflowers under glass frames or lights. Decaying leaves mould on the stem are removed at once, and it is of much benefit to the plants to stir the ground amongst them.

### CUCUMBER HOUSE.

In many families the supply of Cucumbers is a most important one, and at this time it is difficult to obtain a full supply them. Under the best conditions, with good management however, winter Cucumbers may be produced with a tolerable degree of certainty. For winter the best form of house is the half-span, and perhaps this form is as good as any other for all seasons. The plan pursued at Loxford Hall is to have a moveable trellis which is as close to the glass in winter as it possibly

can be without causing the leaves to come in contact with the glass. It is also arranged in such a manner, that as the season advances and the sun's rays become more powerful the trellis can be lowered without in any way interfering with the plants, which are simply lowered with it. At midsummer the leaves are at the furthest distance that the arrangement of the trellis will allow. In previous numbers the details of management have been given; little can be added, except to insist on a moderately moist condition of the roots and of the atmosphere. Steaming the pipes has been tried, but it does not benefit the plants, and may even do harm. By steaming is meant wetting the pipes with water from a syringe or fine rose until the house is densely filled with vapour.

#### PINE HOUSES.

In the fruiting house the largest proportion of plants are now throwing up fruits. For the next two months the average minimum temperature will be 60°, the maximum temperature will not rise higher than an average of 65°. The evaporating troughs are not used in any of the houses during winter, damping the walls and paths about once daily is sufficient for atmospheric moisture. But very little water is required to the roots of the plants; perhaps twice during the same period will be sufficient. The fruits will ripen in May and up to the middle of June. Other plants in the same house will not throw up until the temperature is increased early in February. Such plants will not be watered at all until that time. It will thus be seen that while one set of plants are swelling their fruits another set of them are at rest, and a compromise has to be made in the winter treatment.

Succession houses do not have quite so high a temperature: 55° is the best minimum, and lower than that is not desirable, if indeed it would not be positively injurious to the plants; and instead of well-shaped fruit, badly-formed worthless examples would be obtained. It is many years since I had charge of a very fine lot of Pines. The plants had been grown under my own care, and so fine were they that the greatest expectations were formed as to the results of their fruiting. Unfortunately the plants had to be removed to a house where the temperature in severe weather could not be raised to 55° at night, and it would often be 50°, sometimes as low as 45°. When the fruit showed in the spring it was to me a great disappointment to find the largest proportion of them were miserable abortions.

Admit air on all favourable occasions; unless the weather is very cold, air ought to be admitted every day.

#### PLANT STOVE AND ORCHID HOUSES.

We are trying a lower temperature in this department this winter; 65° has usually been our minimum temperature, but for at least two months from this date 60° will be the minimum instead of 65°. The only plants that would be likely to suffer from the lower temperature would be *Phalenopsis grandiflora* and *P. amabilis*, also the Pitcher-plants, such as *P. Rafflesiana*.

Some extended remarks were made in a previous number about the Orchids and other plants in flower, and such as are useful for decorative purposes from the beauty of the foliage alone. To them may be added *Poinsettia pulcherrima*. The plants are now in great beauty, and the lower leaves which add so much to the effect have been retained more so than usual. How often does one see this fine plant almost denuded of leaves, the floral bracts stunted and dropping off prematurely! What is the reason of this? may be asked. The reason in most cases is this, that the plants are grown-on during summer in an over-high temperature and in hungry soil. The *Poinsettia* delights in rich substantial turfy loam, and our plants have been watered with guano water almost as strong and quite as frequently as it has been applied to *Chrysanthemums*. During the summer months the plants were placed in a sheltered position out of doors, and were removed to the stove or Pine houses in September. Many stove plants are greatly benefited by being placed out of doors; and if, as is too often the case, mealy bug is present on them, it will not thrive in the free air and frequently chilly nights of August and September. *Gardenia florida* is very greatly benefited by this exposure, and we had, perhaps, the best bloom from *Dendrobium nobile* when it was placed out in front of a south wall freely exposed to the summer's sun. Considerable care is requisite in watering at this season. It is always best if rest can be given to any plants during such dull weather as we have at present.

#### FLOWER GARDEN AND PLASMURE GROUNDS.

Preparations must now be made for the flower beds next season. Sticks and pegs are made ready during inclement weather. Where there are plantations and an undergrowth of brushwood plenty of material can be obtained for either purpose. The sticks may be cut into convenient lengths and tied-up in bundles. When the sticks are being trimmed pegs may be made of the spray, and the different sizes of each should be kept together.

We take the first favourable opportunity to mulch the Rose beds, also round the roots of isolated specimens, with short rotted manure. The best time to do this is when the ground is hard with frost. Very few need be told that all wheeling

with barrows is best done in hard weather, when the barrow wheel runs over the ground as it would along a smooth plank. In fine weather sweep and roll the walks and lawn, and much may be done by looking over the shrubbery, cutting out all dead or decaying wood, and cutting back branches that have grown out of place. Even Coniferous trees are much improved by having any side branches that have taken the lead cut back; this encourages a more even growth. Mulching over the roots of such trees, as also *Rhododendron* beds, is very beneficial. The *savants* have given notice of a severe winter, but even without any warning it is best to be prepared by having a thick mulching over all tender subjects and protecting material at hand to be used in case of an emergency.—J. DOUGLAS.

#### TO CORRESPONDENTS.

BOOKS (*A Subscriber*).—We do not know Newton's pamphlet.

REMOVING ROSES (*Brier Cutting*).—If the shoots are hard and well ripened you may safely remove the plants now, pruning closely in March, but all that are weakly should remain in the cutting beds another year.

GAS LIME FOR DESTROYING SLUGS (*M. H. H.*).—It may be safely sprinkled thinly on the Rose beds and also round Carnations, but must not be in contact with the plants.

PLANTING STRAWBERRIES (*Caution*).—The land would be better trenched two spits deep, half the manure being placed between the top and bottom spits, and the other half upon the surface. Ploughing 7 or 8 inches deep, however, would answer, giving the amount of town manure you propose before ploughing, doing the work at once, so as to give the land the benefit of a winter's frost. Couch grass, dock, dandelion, plantain, and other deep-rooted weeds should be thoroughly cleared, as these coming up in the Strawberry plantations are extremely troublesome. Plant in rows 2 feet 6 inches apart, and the plants 3 feet asunder in the rows. You may calculate upon a pound weight of fruit per plant in a good season, but an allowance of at least half should be made for loss from adversity of seasons. Planting in March you will not have any fruit worth mentioning the first season, but a full crop the season following.

ASALIAS LOSING THEIR LEAVES (*A Subscriber*).—It is usual for them at this time of year to lose some leaves, but not to the extent yours are doing. It may be due from the plants after the buds are set being kept in too dry and warm an atmosphere, with probably insufficient watering and exposure to too strong light, or by the plants having been kept moist, shaded, and in strong heat, for the formation of wood and buds. Without, however, having particulars of treatment we can only conjecture the cause of an undue falling of foliage.

SEED FOR SOWING A QUARTER OF AN ACRE (*Anxious*).—Long Carrots (the best being Altringham or Long Surrey, the latter best for house use, or if the soil be shallow, Red Intermediate), 2 lbs. of seed; Parsnip (Hollow-crowned is best), 1½ lb.; Flat Poll Cabbage, which we presume is the Large Drumhead, ½ lb. if transplanted, or if drilled, ½ lb.

EARLY POTATOES (*Idem*).—The best early Kidney Potato for market purposes is Myatt's Prolific Ashleaf, and the best very early round is Early Goldstream. A better cropper but later is Early Oxford. Do not plant until March, being careful not to remove the first sprouts, and if they have sprouts when planted half to three-quarters of an inch long all the better, planting the third week in March, if without sprouts about three weeks earlier.

LOMARIA GIBBA UNHEALTHY (*J. S.*).—We do not think the plant would suffer in so short a time from imperfect drainage. A more likely cause is injury to the fronds from too drying an atmosphere or an attack of insects, probably thrips, which you could have enabled us to determine had part of a dead frond been enclosed to us. We should not cut away more than the dead part of the fronds, and beyond rectifying the drainage and any sodden and sour soil, replacing with fresh, we should not interfere with the roots; keep the plant in a rather close and moderately moist atmosphere, affording a temperature of 50° by day, and night 45° to 40° during the winter months from fire heat, which will, of course, be higher in mild weather from natural agency. When the plant commences throwing-up fresh fronds rest, cutting away the old fronds, and encourage growth by a rather higher, closer, and moister atmosphere.

EVERGREENS FOR A S.S.W. AND E.S.E. WALL (*G. T.*).—The galvanised wire trellis ought not to be fixed 1½ to 2 inches from the wall, but three-quarters of an inch. The following would succeed on either aspect:—*Ceanothus aureus*, *C. floribundus*, *C. Lobbi*, *C. integrifolius*, *Edwardsia microphylla*, *Embothrium coccineum*, *Escallonia macrantha*, *E. monticola*, *Garrya elliptica*, *Ignostemum japonicum*, *Magnolia grandiflora* (Kilmouth variety), *M. grandiflora floribunda*, and *Buddlia globosa*. Suitable climbers would be *Lardisbala biterata*, *Jasminum officinale grandiflorum*, *Pamissora cuneata*, *Cepitellum odoratissimum*, *C. sempervirens floribundum*, *Berberidopsis corallina*, *Elgonia grandiflora*, *Glycine sinensis*, and *G. frutescens magnifica*, *Orydala japonica*, and *C. japonica princeps*; but some of these are not evergreen, and are not so good for giving an evergreen clothing to a wall as the first-named.

INCLINING THE SURFACE OF TERRACES (*J. P. of York*).—We have two terraces, each about 24 feet wide, with an incline on the flat part of a foot each outward to the slope, and no one can tell that the surface is at all inclining. We should not hesitate to give an 18-foot terrace an incline outward of 9 inches, and the other of 27 feet an incline of 12 to 15 inches, but be careful to have the surface regular, and the slopes of the same height at the ends and throughout their length. An incline in a terrace is the most noticeable and objectionable when it is inward, but a slight incline outward—i.e., from the eye at an elevation, is if anything an improvement, as a terrace quite level always appears as if inclining inward. We do not know whether the landscape gardener you name is still practising.

STELLARIA GRAMINEA AUREA.—"ONWARDS" asks if the Golden Feather is to be superseded by this *Stellaria*. Will some of our friends state their experience?

HOT-WATER PIPES IMPROPERLY VARNISHED (*W. H.*).—The fumes given off by the pipes when heated causing the leaves of Geraniums to shrivel and fall, will continue to be given off for a long time, especially when highly heated. It would be the most preferable plan to remove the tar varnish with caustic

potash. Dissolve the potash in water, mixing with freshly-slaked lime, and after the mixture has settled pour off the clear liquid for use, keeping the pipes wet with the liquid, and removing the varnish with a coarse cloth; but a still better plan is to remove the pipes, and making-up a wood fire burn-off the tar varnish. The best paint for hot-water pipes is made of lamp black mixed to the proper consistence with linseed oil, and applied to the pipes whilst hot.

**CUCUMBER LEAVES SHRIVELLING** (*A. B. C.*).—The plants are probably affected with disease, the symptoms you describe being attributable to it. There is no known remedy, but it is most prevalent when the soil is rich and with too much moisture in the atmosphere, and a high night temperature, with a defective arrangement for bottom heat, it being too low.

**BOILER** (*E. T. S.*).—There is practically very little difference between the boilers named, both are good. Either would suit you. Your present boiler is a good one, and must be of too small a size for the work it has to do. By raising the boiler you would lose heat, as the size of the furnace would be increased without increasing the surface of the boiler for the abstraction of heat. A great waste of fuel is the result of a large furnace with a small amount comparatively of boiler surface exposed to the direct action of the fire. Hollow grate-bars do not prevent clinkering, as anyone having the stoking of them can testify. No boiler with the return pipes at the lowest part of the boiler, and the flow at the upper part, can possibly have the water in the return pipes hotter than in the flow pipes without the circulation of the water being obstructed, and this is what we think is the matter with your apparatus—improper arrangement. The fire acting on the boiler, the heated water should rise by the flow discharging the cold, which from its greater gravity will sink to the lowest point, and the return pipes are consequently the coolest until such time as the whole volume of water becomes heated. Any result different to this is indicative of defective arrangement.

**STURMER PIPPIN A KEEPING APPLE** (*E. F.*).—Your fruit-room must be in fault. It is one of the longest keeping. In 1867, July 26th, we had on the table Early Harvest Apples of the same year, and Sturmer Pippins of 1866.

**BOWING BRIDS OF SHRUBS AND TREES** (*E. K.*).—All the trees and shrubs named in your list would succeed except Nos. 1, 9, 13, 18, and 14. We do not know the Honeysuckle you describe. Of *Opuntias* you may add *Lambertiana*; of *Pinus*, *Cembra* and *Laricio*; of *Juniperus*, *chinensis*, *communis*, and *drupacea*. *Peat* earth shrubs would not succeed in the seedling state unless you were to give them from 4 to 6 inches of soil of that description, and at no time would they do well in a soil such as yours appears to be. The best variety of hardy *Daphne* for pots is *D. Cneorum*.

**IRON PILLARS FOR BOWNS** (*E. I. S.*).—You can have iron stakes of inch-round bar iron, which should have four prongs, each of about 18 inches in length, for securing in the ground, or you may have the iron rods leaded into stone. We should not, however, have solid iron, but procure lengths of wrought-iron piping 1½-inch bore, and let the sockets and into stone 6 inches and run with lead. The stones should be about 15 inches square and covered about 4 inches deep. The pipes should have four coats of red-lead paint. To keep water from the pipe a screw cap or plug may be employed. Any ironmonger would supply the pipes, and any mason would fix them in the stones. A wire from each pillar would do more harm than good, as they are in a curved line, unless you were to have a stay to each and on the inside of the curve.

**MUSHROOMS FAILING** (*An Anxious One*).—Our Mushroom beds have stone shelves for bottoms, and answer admirably; they are about the same depth as the description given of yours. We are not surprised at the failure when you inform us that "pieces of spawn were thrown in at the time of making-up." We give a brief summary of our practice, from which you may probably glean the information that will secure success in future efforts. Fresh horse droppings are collected with a portion, about a fourth, of short litter, and laid thinly in a dry airy place, and not so thick as to heat. When a sufficient quantity is had to make a bed of 15 inches to 18 inches in depth—which we can obtain in about three weeks by shaking out the long litter, freeing the short of as much of straw as may be done with a fork, and placing it in a ridge-like heap on one side until the whole has been shook out—we take the short litter, which will have been well mixed, the fresh being placed at the bottom and the heated at top; and though we have tried the fresh droppings not allowed to heat, and the litter shook out of the manure heap not older than three weeks, we failed to notice any difference in the result. The dung is placed in the bed 2 inches thick, and beaten very firm with a wooden mallet about 6 inches square, and with a short wood handle. Layer after layer is put on the bed, and each layer is beaten as firm as the first, and the whole is made to have an even surface and of equal depth—not less than 15 inches, nor exceeding 18 inches. The heat will have declined to a suitable spawning temperature in about ten days. Not until the temperature has fallen to 90°, and before it falls to 75°, the spawn must be inserted. The temperature at which to spawn is that of the bed 4 inches deep. The spawn (fresh is best, which, if it is good, will smell very strongly of Mushrooms) is broken up into pieces about 2 inches square, and inserted so as to be covered about 2 inches deep, and after spawning a light beating is given the bed so as to firm the dung over and about the pieces of spawn. In a week or ten days after spawning the bed is earthed 2 inches thick with rich turfy loam chopped-up rather fine, and in a condition as regards moisture that it may be beaten very firm without forming a muddy mass, and yet be a close, compact, hard surface. In six weeks the bed will have Mushrooms appearing on its surface, or soon afterwards, and should be lightly watered, and after this be kept moist, but avoid making the soil very wet—just moist is sufficient. The floor and walls as well as the bed should be sprinkled with water and kept moist, for the Mushroom is impatient of a dry atmosphere. The house must be dark, and the temperature 55° to 65°. The sample of spawn was good.

**COLOR-WASH FOR GARDEN WALL** (*Lady C.*).—A solution of carbolic powder with water and thickened with lime to the proper consistence would be a good mixture to apply to the old wall. We should add soot sufficient to tone down to a dull grey or very light lead colour as may be most agreeable. By mixing a small quantity, and applying it to the wall, letting it become thoroughly dry, more or less soot can be added to make the wall lighter or darker as desired. Wash the wall at once, choosing dry weather; a brush would be preferable to a syringe to apply the solution, which should be thoroughly brushed into the seams and crevices.

**NAMES OF FRUITS** (*W. Dawber*).—1, Gloria Mundi; 2, not known; 3, Loane's Pearmain; 4, Bull's Golden Reinette; 5, Herefordshire Pearmain; 6, Nonpareil Park. (*F. F.*).—Van Mons Leon Leclerc. (*J. P.*, *Highgate*).—Monsieur Jean. (*Connaught Subscriber*).—1, Oranienne; 2, Beurré Diel; 3, not known. (*Lady C.*).—Neither of the Apples is the old Golden Pippin. No. 1 is Franklin's Golden Pippin, and No. 2 the Stone Pippin. (*W. A. K.*).—1, Beurré Diel;

2, Beurré Bosc; 3, Beurré Rance. (*F. Jellico*).—The Apple is Gloria Mundi, and the Pear Doyenné Boussoch.

**NAMES OF PLANTS** (*Mrs M. May*).—The specimen is very imperfect. It appears to be *Trachelium caeruleum*. (*M. I. B.*).—1, *Nephrodium retigerum*; 2, *Pteris arguta*; 3, *Adiantum cuneatum*; 4, *Polypodium appendiculatum*; 5, *Asplenium nidus*; 6, *Aspidium (Oxytomum) falcatum*. (*J. S.*).—*Dendrobium affine*; very healthy and vigorous. (*Senae*).—*Encymus encypus*, the Spindle Tree or Frickwood.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### BIRMINGHAM POULTRY SHOW.

Once more we are in Bingley Hall. The great Show has come round again, and with it "cattle-show weather," as they call it in Birmingham—i.e., a mixture of frost, fog, and sleet; but this matters little in Bingley Hall, where we are too much interested in the yearly contest in many a class to think of the temperature outside. The poultry, alas! save Geese and Turkeys, are not in Bingley Hall proper, but in the same annex as before—a draughty place, its sides overhung with galleries, which cause many pens to be seen to great disadvantage. We used to look upon the Birmingham Show as an institution venerable from its antiquity, and like many such institutions somewhat out of date and needing internal reform. The reforms, however, come tardily indeed, but they do come at last. We observed several innovations last year, among them the displacement of Dorkings from their old position in favour of Brahmas, which, by-the-by, we do not consider an improvement, and this year we see more. Pigeons are shown singly; the objectionable water dishes on the floors of the pens have been replaced by zinc vessels hung up, and we have watched officials distributing chaff in the pens. There are many more practical reforms which occur to us as desirable: The awards might be posted up in some more systematic way instead of being written indiscriminately over three or four cards; green food might be given to the birds, and more barleymeal, or better still, Spratt's food and barleymeal mixed. But these improvements we trust to see another year, and rejoice at what we have. The numbers (1960 pens of poultry and 541 of Pigeons) have, we believe, been exceeded in other years; but 280 more than last year, and few classes are not well filled, and any reduction in entries arises, we fancy, from the rise of standards and the consequent inability of sending rubbish. Dark Brahmas head the list. We should not be at all surprised, after what we have heard and seen lately, to see this popular variety fall off somewhat in estimation; they do not fetch the price they did, and the wheel of popularity seems returning again, as it always must, to the most valuable of English fowls—the Dorking.

**BRAHMA, Dark**, cocks are a good class with thirty-seven entries. As a rule they are well through the moult and in good condition. First as usual is Mr. Lingwood. We only hope that his well-merited successes will not drive other fanciers to abandon the breed. The first and second prize birds happened to be opposite each other, and we had a good opportunity of comparing them. We thought the awards good, the first being the broader bird and best in the rise of back towards the tail, and the most heavily feathered on leg. We preferred, however, the deeper stripes on the hackle of Mr. Ansall's bird. Third is a slightly hooked bird, well-shaped but too long in tail. We did not much admire the fourth. His comb is too high behind and inclined to a peak. Among the highly commended is a bird of Lady Gwydyr's with splendid foot-feathering, a nicely shaped hooked bird of Mr. E. C. Peake's, and a strikingly large one of Mr. Lingwood's. **Cookerels**.—First is a cockerel almost faultless in size and points, though we have seen better combs. Second a beautifully shaped bird apparently young, for his spurs have hardly appeared. He has a neat Brahma head; his hackle-markings are light. Third is a very dark bird, small, and higher in back than we like. His foot-feathering is prodigious, but does not extend well up the leg. We should have put the fourth third; he is a little deficient in breadth of back towards the tail. Fifth a narrow bird, but he has a good black breast and beautiful orange-coloured legs. **Hens**.—The first winners are we think well known. One of them not very good in leg-feathering; but they are grand hens, evenly pencilled all over. Second are a little brown, good in shape and size; third are fair in pencilling, heavily feathered on legs, still a trifle brown, and one not so sprightly as her companion; fourth fine in shape, with pencilling like that of Mr. L. Wright's strain. **Pullets**.—Certainly the Crystal Palace does show off all birds to advantage, though the superior birds are chiefly the same as those we saw there; they do at Birmingham look strangely different. To the first pair of Dark pullets was awarded the twenty-guinea cup for the best pen of Brahmas in the Show. An exquisitely-pencilled pair they are, just the type of birds which last year were bred by Mr. Peake—not very large or heavily-feathered, but with the fine truly Brahma head; of a beautiful ground colour, and crisply and uniformly pencilled all over. Second did not look to us like Mr. Lingwood's best; their wing and back marking is beautiful, but they are a trifle light on breast. Third a Night-

coloured pair, evenly pencilled all over, but very poor in leg-feathering. Fourth somewhat indistinct on the breast for a prize pair. In the fifth-prize pen one pullet was better than the other. Mr. Birch's highly commended pen (140) contained one enormous bird, we almost think a hen sent by mistake. Mrs. Baillie Hamilton showed a singularly well grown pair, highly commended.

**Light Brahmas** almost equal their Dark cousins in aggregate numbers. The pullet class of the variety is peculiarly strong, and a highly commended is no barren honour there. **Cocks.**—The first prize goes justly to Mr. Horsfall's beautiful Palace winner, and the cup too. He certainly looks small here among giants, but he deserves his honour. We described him in our Palace report. Second and third are fine birds, with little to choose between them; they are both larger by far than the cup bird, but do not show his marvellous style. Fourth is rather loose in wing, and spoilt by a huge comb. We think the four prize birds well placed. **Cockerels.**—Mr. Horsfall repeats his double first in cocks, as at the Palace. If his cockerel had a prettier comb it would be an admirable bird. Second not a large bird, but neat all round and fine in foot-feathering. He fetched twelve guineas at the auction. Third another of Mr. White's birds, deficient in neck-hackle, but good in shape and very white. Fourth a fine bird in shape and size; we should have put him second. Fifth rather narrow. Several nice birds, among others Mr. Tedd's (192), would have been higher but for a yellow tinge. We admired one of Mr. Dean's highly commended birds, but he has not enough neck hackle. **Hens.**—The cup went to a magnificent pair, not a good match, however. The best of them is the first Palace bird, a marvel in shape and size, but not looking happy at Birmingham. We hope she will not be overthrown. Second again are not well matched. One of them is superb in shape, and would thus match Mrs. Tindal's best bird, but is deficient in hackle. Third a nice healthy-looking pair of hens, well hackled, but without the massive look of the first and second winners. **Pullets**—number sixty-eight pairs. The average quality is very high, and they must have given much trouble to the Judge. The first are a large pair, clear in hackle and ground colour, and must make magnificent hens, for they look hardly full grown. Second again an excellent pair, splendid in foot-feathering. Third a square and well-feathered pair. Fourth well grown, one better marked in hackle than the other. Fifth one of the best-shaped pairs in the class, but light in tail. Thirteen high commendations and seven commendations testify to the excellence of this class. The shortness of the days has not given us time to look over the **Brahma Selling** classes carefully. They seem a success, as bringing good and cheap birds into the market. The three first pairs of hens sold respectively for £8, £5, and £6.

Mr. Teesbay judged all the Brahmas, and must have been well employed on Saturday.

**DORKINGS.**—The Dark variety certainly do not muster the number of entries which we remember at Birmingham eight or ten years ago, but the quality is very good, and in most cases their colour too; indeed, we are afraid there is a growing tendency to regard them too much as birds of feather. **Cocks.**—Here Mrs. Arkwright is in her old position, and takes second prize as well as first cup. The first cock is square and massive, a little shaky on his legs; he is light in colour and splashed on breast, but has a good black tail well moulted-out—a merit, and one often overlooked. The second is a very similar bird in colour, though not so square in make, and carries his tail too far back. Third a very tall and dark bird with excellent white feet, a little wanting in breast. Mr. Darby's highly-commended bird and Mr. Bartrum's unnoticed one are both grand cocks, but not in their best plumage or condition. **Cockerels.**—Mr. Burnell is first with a gigantic young bird, which we commented on when second at the Palace. Second a large and long cockerel, but we do not much admire him; he is white in earlobes, and one of his middle toes twisted. Third a squirrel-tailed bird, good in feet and comb. Fourth a large bird, good in legs and feet, very brown on the wings. Fifth strong in limb, of a good dark colour. As a whole the cockerels were certainly not in such strong force as we have seen them, at the same time there were very few really bad birds. **Hens.**—The three winning pens are all excellent and well placed. The cup birds are fairly a-head, and a magnificent pair. Mr. Bartrum's second pair are rich in colour, and one of them a grand bird, being superior in form and comb to the other. Third are very large, but dusky in feet. **Pullets.**—In this class sooty feet prevail; it seems next to impossible to get white feet with the very dark colour now required. Here again Mr. Burnell heads the list. The first and second prize pairs are nearly equal. First are a well-known pair, second and third at the Palace, their only fault being dark feet. Second a deep-bodied rich-coloured pair, white in feet; they come from Ingham. Mrs. Arbutnot's mantle seems to have fallen on her successor! Third well placed, one specially good. A nice pair of Mrs. Arkwright's are unnoticed, we suppose as being too in-kneed. An almost Black pair of Mr. Drewry's are highly commended.

**Silver-Greys** are improving in numbers; among the winners are birds that would well do battle against the Dark variety. The cup cock is very good all round, and easily first. Second has a bad overlapping comb; he is generally inferior to Mr. Rutledge's unnoticed bird, which we conclude was put out by a little white in thigh. **Cockerels.**—We are glad to see Lord and Lady Bagot again exhibiting here. First is good all round, not very deep-bodied. Second a nice silvery little bird, second at the Palace if we forget not. Third very poor, dark in neck-hackle and shoulders. A large and good bird of Mr. Howard's highly commended. The light in Birmingham is very unpropitious for judging silvery birds, and many of this class look yellow, which at the Palace would make a good appearance. **Hens.**—The two winning pens are old acquaintances, both from Mr. Cresswell's yards. The first pair marvellously long in body, and large; the second not quite their match, but very square and thorough Dorkings. **Pullets.**—A fine pair carry off the cup, one of them such a pullet as we have seldom seen. Second are also a good pair, but we dislike their breast colour. In our opinion the breast of a Silver-Grey hen should be either robin-coloured or salmon-coloured, but these and many other good birds now have breasts of two shades of cinnamon.

**Whites** continue to improve, and many grand birds are to be found in the four classes. Combs are the failing in this breed. Mr. Cresswell repeated his Palace victories, and secured both cups. The cup cock is very broad, and by far the truest Dorking in the class. Second is a very nice bird and massive, but he has not the style of the cup bird. In cockerels Mrs. Hayne is first with a very white bird. We think we saw him in the prize list at Oxford and the Palace. He has had his tail broken since then. Second is a fair bird, not very striking. There are many good birds among the unnoticed in this class. **Hens.**—One hen in the first-prize pen is large and good, the other smaller and with twisted hackle. She was third at the Palace. Second a fine pair but with wry combs. Highly commended a very white pair, one of them the cup hen at the Palace. **Pullets.**—The cup went to a pretty pair but not so good, we think, as their owner's highly commended pair, which were in a bad light and seen to disadvantage in a corner pen. Second a good match and in their right place.

In the **Selling** class the first-prize Dorking cockerel is a good bird all round and worthy of the open class. The hens are poor.

Mr. Baily judged all the Dorkings, and we heard few complaints about his awards, which is something to say at Birmingham, where for various reasons it is difficult to make satisfactory decisions.

**COCHINS.**—It is unfortunate that the Buff Cochins are ranged round the annex under the galleries. Their delicate colours require a strong and even light to show them to advantage. The old Buff cocks are not, as a rule, in good feather and condition. First-and-cup is Mr. Burnell's famous bird which needs no comment. Second a bird in poor condition, and not well recovered from the moult. Third one not sufficiently feathered on the shanks, but in better condition. Fourth a nice bird which we should have placed second, rather black in tail, but good in colour and well feathered. **Cockerels.**—Here we could not understand the first award. The bird is certainly well shaped but mealy on the wing, and his black tail does not seem to suit his canary-coloured hackles. Second an evenly-coloured bird and well shaped. We thought him the best in the class. Third a nice bird, a little cloudy in hackle and not equal to the marvels which sometimes come from Stoke Park. Fourth good, not dark enough in wing to match his fluff colour. We much admired Mr. W. A. Taylor's very highly commended bird, the old-fashioned type of Cochin. Among the highly commended we saw Mrs. Tindal's champion Palace cockerel. He has, indeed, made a mighty descent; others do not so well deserve their high commendations. **Hens.**—Mr. Procter's cup pair are magnificent, though not a perfect match. The lighter one is singularly sound in colour. Second a good and well-matched pair of beautiful shape. Third are smaller but very good in shape. The fourth pen contains one magnificent hen. **Pullets.**—First are a very perfect match and even in colour, one of them is too much feathered inside the legs. Second are a pair which will make even larger hens. They are rather darker in colour, especially one of them, which is the best bird. They are not so short on the legs as Mrs. Tindal's birds, and have not such profuse down. Third a smaller pair and unmistakably hooked, but very even in colour. The class is a super-excellent one, and twenty-nine pens are noticed.

**Partridge Cochin cocks.**—The cup bird is nearly faultless all round, splendid in shape and excellent in condition. Second a very large bird with fine leg-featherings, but too round in back, and slightly slipped in wing. Third rich in colour, not very gainly, but, barring some white in his tail, better, we thought, than the second. Mr. Tudman's very highly commended bird is good, a little too darkly striped in hackle. The cockerels were in a dreadful light, and no judge or critic could do justice to them there. Mrs. Tindal's first cockerel is very near perfection, and will make a larger cock than the cup bird. He does

not carry his tail quite to our fancy. Second a pretty bird, not heavily enough feathered on shank, and his legs are too near together. Third very good, but less than his owner's other bird. We much admired the shape of Mr. Bennett's very highly commended bird; and Mr. Perival's highly commended bird would be a winner in most shows. Hens.—Breeder of this variety seem to stick to it. Mr. Stretch is a veteran exhibitor, and is not behind the times. His cup hens are magnificent in size and form, and more Grouse-like than most winners of late. Second fine in penolling, good in form, and fairly large. Third crisp in penolling, but not a match; the smaller one is good in shape but has a bad comb. Pullets.—We are glad to see that "Brown" is not merely a name in schedules and catalogues now, but that many darker birds are not only shown but win. The first pullets are excellent, one in particular; they are well marked on breast and wings, especially considering that they are of the darker colour. Second are not so big a pair, but well matched, and their penolling is like that of good Dark Brahmas. Third in cinnamon darkness appeared to us good and of a rich brown colour.

**White Cochins.**—The cocks are a magnificent class, and in better feather than most old birds. We fancy this may result from the breed being so much kept indoors. The cup bird is spotlessly white, and perfection in leg-feathering. His back does not rise quite enough towards the tail to please us, but this may only be the result of the discomfort of a pen. Second a little hooked, with a well-shaped comb, a bird which we think does not show himself to advantage in a pen. We preferred the third; he is very white and finely feathered. Mrs. Acton Tindal's very highly commended bird, though small, is stylish, and just the form we admire. Cockerels.—No. 1 is low on leg, magnificent in thigh, fluff, and leg feathering; 2 a big bird, which should be a better cock than cockerel; 3 a nice short-backed bird, rather yellow. We like an unnoticed bird of Mr. Tomlinson's; heavy feathering inside the legs must have pulled him down. Hens.—The cup pair are very grand. We have not seen such since the days when Mr. Woodgate gained a series of victories with two renowned hens. Second are smaller but very white, and we thought one in shape the most perfect model we have ever seen. Third were far from the first and second, possibly scurfy on the legs, but one of them good in shape. Pullets.—The first are much a-head; the same type of birds as Mrs. Acton Tindal's hens. Second a good pair, large and apparently young, a little yellow. Third a pretty pair, rather set in figure, and one yellowish.

**Black Cochins** are making great strides. In cocks Mr. Darby has it all his own way. First is a very pretty bird; he is better and more gainly in shape than most birds of the coloured varieties. The better Blacks certainly have much of the shapely form of the early-imported Cochins. Second is a little too high in comb, and does not rise quite so well in back towards the tail; his legs are yellow. Hens.—The first-prize pair are large, but we do not think them the best in the class. One has a high, twisted, white comb, and the white extends on to the side of the head; her beak too is very crooked. Mr. Hargreave's pen (918) were too late for competition, or they must have won. One of them is a true Cochins in form. Second are a well-formed pair of pullets, one of them somewhat under-feathered. Two pens received very highly commended cards, which testifies to the improvement in the breed, for not long ago it was difficult to find pens fit for prize cards. Mr. Hewitt judged the Cochins and Malays.

**Malays** have some faithful admirers, but they never can become a popular breed. The first cock is an enormous very dark bird with willow-coloured legs, which struck us as a blemish. Second a less bird of bright colour; a nice White is highly commended. The class for cockerels is good. First a magnificent bird. Second, too, will make a fine cock. The cup hen is good and moderately dark. Second very dark; a light cinnamon one receives a very highly commended. The first pullet is very hard in feather and clean made. The second took our fancy—an immense bird of a rich dark brown colour.

**Chevrons** have but two classes. They have been beaten by their Houdan cousins—a breed more suited to our climate. The first cock is not very large but in spruce condition, glossy and black in tuft with a splendid beard. Second a large bird with little beard and very irregular tuft. Third looks old and done-up, though large; he has the most enormous tuft we ever saw. Mr. B. Fowler's highly commended bird appeared to us a perfect model Crève in form, though a little undersized. Hens.—The cup pair well deserve their honour; they are grand birds and black in tuft. Second good also, though not so large. Third a little brown but well placed.

**Houdans** must certainly be most hardy birds, the old cocks look so well-moulted and sprightly, and this too in the most draughty part of that most draughty building. We are glad to see that the Judges are not now going in solely for the very dark birds; the winners are for the most part evenly speckled and moderate in darkness. The first-and-cup cock is a noble bird in form, but shows an inclination to colour in neck-hackle and wings.

Second, an evenly-marked bird, handsome in tuft and head and bright in condition. Mr. Dring has a good dark bird unnoticed. Cockerels.—The Judge must easily have "spotted" the first; he is inclined to be dark, with a splendid beard. Second is a splendid bird, which we liked much. These classes must be difficult to judge; we know no birds which look so different at different times in a pen as Houdans do. Hens.—Mr. Vallance's first hens are magnificent, very evenly speckled; their combs are singularly globular for Houdans, and their heads large. Second are much the same in colour, but less. 1083 (Quibell), highly commended, good. Pullets.—Houdans must be a variety which grow late, for there is much difference in the size of hens and pullets. First pair are not very remarkable, one of them has already some scale on feet; second have fine tufts, but one appeared to us wry-tailed; third we liked as well as any in the class.

Mr. Bally judged all the French classes.

**SPANISH.**—Decrepitude seems too much the normal state of Spanish cocks. In this class Mr. Jones takes both prizes and the cup. His birds are very smooth in face; the wattles of the second are very open—an eyesore, in our opinion. Cockerels.—We much like the form of the first. His tail feathers are well formed and grown—a minor point certainly, but still not to be forgotten when so many rotten-tailed birds are shown; his face is large and not abnormally developed. Second has a well-serrated comb, a nice face and indifferent carriage. Third a smaller face, but he is a pretty bird in good condition. Hens.—The cup hens are fresh-looking, with good round face. Second another excellent pair in blooming condition. Mrs. Allsopp's birds do credit to her feeder. Pullets.—Both prize pairs are good in head and condition, the first slightly the largest.

Mr. Bally judged the Spanish classes.

**HAMBURGERS.**—Black Hamburgs are fortunate in having two cups offered them, but the birds shown well merit them. The variety now seems a popular and a thoroughly-established one. The first cock is perfection in comb, colour, and style. Second not quite so stylish, but very good. Third one of the brightest-coloured birds we have ever seen; his sickles are fine, and his comb as nature made it. There are many other excellent birds in the class. Hens.—The cup pairs are beautiful in form, gloss, and comb. Second well placed; their combs are even and pretty. Third are not quite so perfectly matched. We fear Mr. Serjeantson must be giving up the breed, his birds are priced so low.

**Golden-pencilled cocks.**—The cup goes to Mr. Walker's beautiful bird, which we have noticed in a former report. Second carries his tail too much up, his comb is natural, his neck-hackle dark. Third somewhat too coppery in tail, and with a flaw in comb; he is an old bird. We like Messrs. Duckworth's highly-commended bird. *Silver* cocks are few, and not very good. First has a pretty comb and fine sickles, fairly edged. Second shows a little brown in tail. Third is younger, and a pretty little bird.

**Golden-pencilled hens.**—Here the Judge has gone in for the smaller and finer barring. The first pair are both well-barré, one better than the other; their ground colour is rich. Second a pretty pair, better marked on breast than one often sees them. Third not well-barré in tail. Good birds with the coarser barring are shown by the Duke of Sutherland, Messrs. Duckworth, and Mr. Davison. *Silver* hens.—The cup pair are singularly clean in neck-hackles, and well-barré all over. Second and third fair average birds.

**Golden-spangled cocks.**—The cup bird has one of the best combs we ever saw on a spangled bird. He is marked "sold." Second is not so heavily spangled, and has not such a good comb. We preferred the third, a very large bird. *Silver* cocks.—We do hope that combs are now less trimmed in these classes than formerly. First is a noble bird with grand carriage, fine comb, and round spangling. Second too heavy in comb, well marked. Third not perfect in comb, but we like his round spanglings. Hens.—The cup is awarded to the first Golden pair; they are beautifully marked, but certainly the hens of this variety do not equal the Silvers in form. Second are in better condition than most birds in the class. Third with small very round spangling. *Silver* hens.—First are very pretty, their spangling moderately heavy. Second much the same, but not so well marked on wing. Third have smaller but very even spangling. All the class are remarkable for good condition. Mr. Dixon judged the Hamburgs.

We must defer our criticism on the remaining poultry classes till next week, so many are they, and require careful inspection from the closeness of competition. We may remark as a postscript that since we wrote the earlier part of our report green food has been given daily to all the birds. We thank the authorities gratefully for this attention.

Mr. James Walker's first-prize White gander and Goose weigh 58 lbs. 9 ozs.; Mr. J. K. Fowler's second-prize White gander and Goose, 53 lbs. 4 ozs. Mr. James Walker's first-prize Gray gander and Goose weigh 51 lbs. 9 ozs.; Mr. F. E. Richardson's second prize, 39 lbs. 6 ozs. Mr. Edward Arnold's first-prize Turkey

cock weighs 83 lbs. 12 ozs.; and Mr. W. Wykes' second-prize Turkey cock, 84 lbs. 8 ozs. Mr. H. J. Gunnell's first-prize Turkey cock, hatched in 1876, and seven months old, weighs 29 lbs.; and Mr. W. Wykes' second-prize Turkey cock, six and half months old, weighs 24 lbs. 10 ozs. Mr. George Daft's first-prize pair of Turkey hens weigh 50 lbs.; and Mr. E. Kendrick's second-prize pair, 40 lbs. 8 ozs. Mr. W. Wykes' first-prize pair of Turkey hens, six and half months old, weigh 82 lbs. 3 ozs.; and Mr. E. Arnold's second-prize pair, 81 lbs. 12 ozs. Mr. James Walker's first-prize Aylesbury Duck and drake weigh 21 lbs. 9 ozs.; and Mr. J. K. Fowler's second-prize Duck and drake, 20 lbs. Mr. James Walker's first-prize Rouen Duck and drake weigh 20 lbs. 6 ozs.; and Mr. Robertson Gladstone's second-prize Duck and drake, 19 lbs. 10 ozs.

#### PIGEONS.

In this department of the Bingley Hall Exhibition we have this year one or two innovations, the chief of which is the introduction of the single-bird system throughout the whole of the classes instead of confining it as formerly to the adult Carriers and the Pouters. To this, combined with the abolition of the guinea subscription, another subscription instead of an entry fee of 5s. per pen, is no doubt to be attributed the increase in the number of entries from 375 last year to 541 on the present occasion. The general quality of the specimens has, to our thinking, also increased in equal ratio, for the very fact of exhibitors having to show a pair of good birds instead of only a single specimen no doubt often kept many celebrities in their owners' lofts, or caused them to be sent to other places where the single-bird system was adopted, simply on account of the immense difficulty of obtaining suitable matches. In the pair system accuracy in matching is the chief element of success, and often pulls off the prize in favour of inferior birds in regard to general properties over competitors of higher quality on the whole, but lacking in this one respect. To win in the show pen a pair must be a pair in every sense of the word: hence the improved quality of the Show generally on the present occasion. Another innovation, and one which we do not think is very acceptable to exhibitors, is the reduction in the amount of the first prize from £3 to 80s. The care of the birds while in the Exhibition is again placed in the hands of Mr. J. W. Edge, an old and experienced fancier, and his exertions for the welfare of his protégés will no doubt be duly appreciated by their owners, and this is a point which might be copied with advantage by the managers of many other exhibitions, who too frequently commit to the care of persons utterly unqualified for the task the care of collections of birds worth, perhaps, thousands of pounds. The birds were shown in the usual tiers of pens three deep round the gallery of the poultry bay; but the arrangement of the different varieties was very badly managed. The numbers seemed to run up and down the pens in a very indiscriminate manner, and the Carriers and other varieties which should have been placed high to be seen to advantage were relegated to the bottom tier, and *vice versa*. Having had our say in regard to the general arrangements, we now pass on to a few remarks in regard to the birds.

First on the list stood the Black Carrier cocks, twelve in all, and a very fair collection they are; but the best bird in the class, belonging to Mr. Fulton, was passed over by the Judge on account of having some white feathers underneath. The same thing, at the hands of the same Judge, occurred to this bird at Bingley Hall last year, which gave rise to the controversy in a contemporary as to whether the white crutch and vent is a disqualification in a Carrier. This, however, is not the place nor time to re-open the discussion. As it was, the first-prize cock was deficient in neck and leg, with a good eye and beak-wattle, but somewhat crowded. The second honours went to Mr. Yardley's well-known old Black cock, looking, if anything, better than ever. Third a long stylish bird, but much younger than his more successful competitors. Other birds in this class call for some notice, particularly the highly commended pen of Mr. Maynard's (1860), particularly good in beak and wattle, and altogether a most useful Pigeon; also the highly-commended pen 1856 (Gordin), a bird possessing good eye and wattle properties, and evidently shown in a natural state. Black hens mustered nine good birds, Mr. Heritage's first-prize hen being of very high character and wonderfully developed for her age (eighteen months), having thrown-up eye and wattle sufficient for a bird double her age. She was one of the birds in the winning pair which Mr. Heritage showed at Bingley Hall last year. Second (Maynard) a very stout bird with a good eye, but hollow in front of the wattle. Third (Fulton) a good bird, but of a much finer stamp than the second. The class for Dun cocks brought seven competitors into the arena, Mr. Fulton carrying off the whole of the honours in this class, together with the cup for the best adult Carrier, with the bird with which Mr. Maynard won at the Alexandra Palace Show, where he was claimed by Mr. Fulton at, we believe, £40. He is a very fine Pigeon, and both he and the second-prize bird bid fair to make winners for some time to come. The second bird was a little pale in colour and rather down-faced, but capital in eye and wattle. Pen 1976 (Maynard)

very good, particularly well made-up in wattle. 1972 (Whitehouse) also a good Pigeon, but "tall it not in Gath," very white on the thigh, and highly commended instead of a disqualification as in Black cocks. Dun hens (ten entries), all of very high character; in fact, the Duns, both cocks and hens, this year carry off the palm for superiority over the Blacks. First (Maynard) a very stylish hen, good in eye, but deficient in beak-wattle. She was, we believe, the winning hen at Bristol, second at the Alexandra, and third at the Crystal Palace Shows, and being a young bird will no doubt improve much yet. Second a meritorious bird, her faults being shortness of neck, and beak-wattle too long for our taste. Third we thought a grand Pigeon, certainly rather short in neck, but beautiful in the properties of beak-wattle, colour, and eye, and altogether to our taste a better hen than the first, belonging to the same owner. 1978 (Fulton) unnoticed, an excellent bird in beak and wattle, but no doubt passed over by the Judge, who gave great weight to style throughout, a point where she was deficient. The Any other colour class were an indifferent lot, only three out of the five entered putting in an appearance for the three prizes.

Carriers hatched in 1875.—Amongst the Blacks eleven entries, among them many birds which will no doubt be heard of hereafter. We cannot say that we were very much taken with Mr. Maynard's cup bird. He promises well in the future as regards making-up plenty of wattle and eye, and is a good colour, but he possesses one very great fault in our opinion in being very throaty. The second-prize bird of the same owner is the first-prize young hen at the late Palace Show, and is very stout in beak and wattle for a young hen. Third (Heritage) a very stylish bird, but rather short in face. Pen 1992 (Fulton) a rare-necked Pigeon, and one which shows itself to advantage; excepting a little hollowness in beak-wattle, a capital bird. In young Duns Mr. Maynard again comes to the fore with one of his Alexandra Palace winners, the bird which was the winner at that show being passed over here unnoticed, perhaps on account of being so well developed. Second a good bird, but rather coarse. The Any other colour class does not call for any particular notice.

Pouter cocks, Red or Yellow, had only three entries, Mr. Fulton taking first with a good Red, as he did also with a good hen of the same colour in the next class. The class for Blue Pouter cocks brought six excellent birds, as may be inferred by five out of them being noticed by the Judge. The cup for the four classes of Pouter hens was gained by a fine Blue belonging to Mr. Fulton, which, however, was run hard for it by the Red of the same owner. In White Pouter cocks the Judge evidently gave the preference to the smaller-girthed birds, Mr. Pratt winning first with a tall, graceful, narrow-girthed specimen, but small in crop, Mr. Fulton's second-prize bird being larger in crop, but of stouter build. In White hens Mrs. Ladd was first with a bird of like description as the first White cock; in fact, the points which seemed to have weighed most with the Judge throughout the whole of the Pouter awards seemed to have been principally girth, length, and carriage. In Pouter cocks, any other colour, there were only two birds to compete for the three prizes, but Mr. Pratt's well-known Black being first, and also wresting another cup to his owner from the cocks in the other classes. Pouter hens, any other colour, were not very praiseworthy.

Almond Tumblers had eight entries, cocks and hens competing together. Mr. Yardley carried off the cup with an excellent bird, rich in his ground colour, very handsomely spangled, and good in head properties, Mr. Fulton's second-prize bird being too dark about the neck, with a good flight and tail, and not nicely broken on the shoulder; his third-prize, a hen, being good in colour, but very inferior in head points, being long and narrow. Mr. Ford and Mr. Yardley showed two capital hens, the former being a little out of condition, and that of the latter was about one of the best-headed birds in the class, having other good properties to match. In Short-faced Tumblers Mr. Yardley was again first with the well-known Yellow Agate cock which won first at the Crystal Palace, Mr. Fulton being second and third with a pretty Black Mottle and a poor Kite, the latter out of condition. Mr. Woodhouse's little Blue Baldhead cock won the cup for the Short-faced Tumblers; Mr. South being second also with a Blue, but of a much stronger character than his more successful rival. A neat Red was third. In Beards an excellent coloured Black belonging to Mr. South was first, Mr. Woodhouse following with a Blue.

Long-faced Tumblers, Long-muffed, and Clean-legged mustered very strongly, being largely supported by varieties peculiar to the neighbourhood of Birmingham. In the former class the winners were Black Mottles and Black Saddles respectively; while in the latter class two pens were left out in the cold on account of being entered in the wrong class, their proper place being amongst the Short-faces. One a rich Yellow Mottle would undoubtedly have received at least a mention had it been in its proper place; as it was, the prizes went to a handsome Red and a Yellow Mottle in the order mentioned.

In *Barbs*, an excellent Red rather out of condition won the

cup in competition with the Trumpeters, Blacks being second and third. Mr. Stanley was successful in carrying off first and second honours for Barbs hatched in 1875 with two promising Blacks, the third being a Yellow rather doubtful as to age.

Mr. Fulton won first with a foreign Black Trumpeter, Mr. Shaw taking the second and third honours with a Mottle and a capital White.

A score specimens competed for the prizes for Red or Yellow Jacobins, first going to a very close-hooded Yellow of Mr. Fulton's, Mr. South being second and third, the second bird being a good but large Red. The Any other colour class does not show any very marked signs of progress, the only merit of the winning birds being that they were small and their colours undoubtedly good, but the properties of hood and chain, so much coveted in the Jacobin, were very indifferent, and it seemed as if the Judge, having none of the other properties of the Jack to work on, was thrown on colour as his criterion in making his awards.

*Dragoons* mustered strongly in all the colours, Blues having the preponderance, and in this class we find a new exhibitor carrying off the cup for the best bird in the Show in the face of all the well-known veterans in the fancy; we congratulate him on his encouraging commencement. Mr. Woods was first and second with beautiful Yellows in the next class, the third being a good bird, but rather too heavy for our taste. The first and second Silvers were also heavy, but were aged specimens. The Any other colour prizes went first and second to Whites, and third a very handsome Grizzle.

The classes for Short-faced *Antwerps* in Birmingham, the home of the variety, as was to be expected, comprised *la crème de la crème*, all the known breeders being represented, and the competition was, of course, proportionately severe. Mr. Bradley won the cup with a very fine Silver Dun, shown in excellent condition. The Blues, as usual, were the most inferior as to quality, the best bird in the class being passed over on account of having a stiff wing. In Red Chequers Mr. Gamon's celebrated old cock was first. In Blue Chequers Mr. Ludlow was as usual unapproachable.

In the *Homing* class the birds were not flown. A spirited-looking Red Chequer was first, but to this variety the old adage, "handsome is as handsome does," very appropriately applies.

In *Runts* only the three prizewinners reached 2½ lbs., the others were all considerably under that weight.

*Fantails* were of fair quality, many of the specimens being too large.

The cup for the *Runts*, *Fantails*, and *Archangels* went to the latter for one of the best specimens that has been seen for some time.

We understand that the Judge censured the whole class of *Nuns* on account of trimming.

There were some good coloured birds among the *Swallows*, but the markings were not so good as we have seen them. *Magpies* seemed rather coarse.

In *Turbits*, Red or Yellow, an extraordinary good coloured bird was first, and a good Black won in the Any other colour class, both specimens being the property of Mr. Cresswell.

The *Foreign Owls* were all Whites, and the winners in the English varieties all Blues. This class was well filled, but the general quality indifferent.

The Any new variety class is always an interesting feature in these Shows, duplicate prizes as usual being always awarded. On the present occasion there are forty entries, and the Judge affixing a note to his awards styling them a superb collection, which indeed they are. The two first prizes go to a beautiful Satinette belonging to Mr. Ludlow and Mr. Yardley's handsome Blondinette respectively; the two seconds a Fire Pigeon and a Red Priest; and the two thirds to a Dark Grey Frillback and a novelty, which we think is a cross between a Burmese and a Scandarnou. The rest of the class is made up of Roman Runts, Monks, Turbites in all colours, peaked and plain-headed Ice Pigeons, Pigmy Posters, and Brunsicks, forming altogether a class of great variety and interest.

**BRABHA FOOTRAS (Dark).—Cock**—1, Horace Lingwood, Creeting. 2, T. F. Ansell, Cowley Mount, St. Helena. 3, E. Kendrick, jun., Lichfield. 4, Ryder, Hyde, Manchester. 5, Lady Gwydyr, H. Lacy, J. H. Jones, T. F. Ansell, R. P. Percival, E. O. Peake, Horace Lingwood. 6, F. J. Cotterill.

From observations taken near London during forty-three years, the average day temperature of the week is 48.2°; and its night temperature 34.8°.

## COVERING OUTSIDE VINE BORDERS.

AS this subject has been brought before the gardening world, it has always been under such circumstances as elicited some fresh idea, if not new fact, bearing on its utility or otherwise; but it cannot be denied that even now it is one of those subjects on which divers opinions still exist, and most likely all will never be brought to one mind upon it. As every fresh experiment in the case adds something new on the matter, some little digest may, perhaps, not be without its advantages, the more especially at a time when there is a hope that the discussion raised upon it may receive some confirmation or the reverse by the time the covering is likely to be removed. The experience of past years ought to assist us all in coming to some conclusion on the matter, for it has nothing new about it—in fact it would not be easy to trace backward how long it has been adopted; but the diversity of opinions on its utility leaves much doubt on the mind of the amateur—now-a-days a very important class of Grape-growers—how to act in the matter, especially when one writer strenuously advocates its adoption, and another in language equally strong condemns it. That there may be a little truth in the assertions of both it is easy to believe, and that both may be right under their respective circumstances is also possible, and very likely to be the case.

As has been stated above, the covering-up of Vine borders has nothing new about it; as readers of gardening periodicals will remember the subject having been prominently brought before the world at various times since London administered what I may call horticultural law through his many publications, and coverings of one kind or another have been more or less urged at various times, possibly most so some twenty or twenty-five years ago, when the covering-up of Vine borders by some waterproof covering, as galvanised iron, wooden shutters, or glass, was so much insisted upon, in some cases quite one-half the original cost of the Grape house was incurred in protecting the border from the autumn rains and winter frosts. Then again followed a reaction: those who had ridden the hobby too hard found to their cost that they had run to the other extreme, and covering-up was condemned, to be revived somewhere else and in another form. While at the present day it would not be saying too much if we affirmed that it had as many advocates now as at any former time, but they are of another class, and do not quite follow out the hobby in its entirety as did their predecessors; while not a few that do cover-up their borders do it for quite another purpose altogether to what it was done in years gone by, as will be shown.

There are two distinct purposes for which Vine borders are covered, and which have little or no connection with each other—the one being with an object to protect the border containing the roots of Vines intended to be forced as early as possible, and the other to enable the crop of

Grapes that may be hanging in a ripened condition in the autumn to remain as long as possible without deterioration or decay in any way. The wide difference between these cases is such as necessarily to call for a wide difference in their treatment, and consequently we shall treat them as distinct. Beginning with those intended to produce early Grapes first, we need hardly say at the outset that there is even here much difference of opinion on the utility of a covering, and not a few eminent Grape-growers too condemn it. We nevertheless, to a certain extent, recommend it where circumstances like those we now adduce render the production of early Grapes a matter of importance.

Whatever improvement may have taken place in Grape-growing as a whole—and most certainly marvellous feats have been accomplished—there seems less anxiety to produce early Grapes at the present day than there was twenty or thirty years ago, the direction of growers of late years has been to preserve those that do ripen in the autumn to a later period in the winter and spring in a good condition rather than have fresh fruit ripe at that time. This is so far commendable, as really good old Grapes are no doubt better than new Grapes: hence hard forcing is on the whole less practised than of yore; the late Grapes being often supplemented, or rather succeeded, by those grown in pots, the convenience of most places where there is much glass allowing this to be done, and what is of more importance, better crops from those grown in the ordinary way is the result. Perhaps it may be asked, What has this to do with covering-up Vine borders outside? Well, it has a great deal to do with it; for there is an immense difference between urging on a house of Grapes to have them ripe by the middle of April and having to accomplish that object a month later. In the former case all the assistance possible inside and out will be required to accomplish the object, and many sacrifices made, while the other will be a much easier affair, and most likely the produce superior. In the former case the Vines, I need hardly say, ought all to be grown inside the house where they are more immediately under command; in the latter they may be partly in and partly out, and yet a fair share of success may be expected without any covering-up. But suppose there are cases (and I know there are many such) where early Grapes are wanted as soon as it is possible to obtain them, and the space inside the house is a very limited one for the roots to occupy, and in fact the bulk of these roots are in the outside border, it can hardly be said that to expose that border to the severities of a hard winter can be beneficial to those Vines whose roots ramify in all directions through it, and in some cases as near the surface as to be within reach of the frost; but this latter event is not of often occurrence, as in a usual way the Vine roots lie deeper than to be directly frozen from the top in ordinary years. However, it cannot be denied but that the frost and melted snow must lower the temperature of the soil so as to be quite unfit for the roots of the Vine, whose tops are enjoying a temperature some 80° or 40° higher, the result most likely being that if the roots occupying the

small border inside are not sufficient to maintain the top in a becoming way, the plant pushes out roots from its stem and so feeds on the atmosphere, deriving a kind of spurious nourishment therefrom that fails it later on in the season when that moisture is withheld. Now this all points to the propriety of an outer covering, and we may now consider what that covering should be.

Before entering on this subject I may say that I am no advocate for costly appliances if simple and inexpensive modes can be found to effect the same object, and in the matter of Vine-border covering I do not know that I would make any great sacrifice in the way of appearance so called, because they have usually to be put in use where external tidiness is of less importance than in summer. Nevertheless, to those to whom the looks of a thing is of much consequence, and who do not object to expense, a waterproof covering of some kind that can be removed when necessary will no doubt be found the best for such a purpose; and galvanised iron, wooden shutters, zinc or asphalt frames, or glass lights have all and each their claims to notice, the great thing being to shut off the bulk of the autumn rains and keep out the frost and snow, and, in fact, to retain as much of the heat that may be in the soil in September as can be until as late a period as possible. We have been for several years in the habit of covering-up the border of our earliest-forced vinery with dry leaves when we could obtain them, and generally we have endeavoured to do so early in October before the heavy autumn rains had wetted it to any depth, and as we have made it a point to try and get the leaves dry and the job finished before any great amount of rain fell, the result has in our opinion been satisfactory. We have usually heaped the leaves on for nearly 3 feet high, treading them well, and finished off by coating the whole with a covering of turf, and as the leaves are mostly Beech or Sweet Chestnut, they give off and retain a little warmth all winter. But it is only fair to state here that although the border may be covered when it is in a nice dry mellow state, and the leaves themselves as dry as leaves can well be outdoors, yet when the covering is taken off in April the ground is invariably found wet and soddened, and no doubt would be in a worse condition as a seed bed than one that had encountered all the changes of the winter. I mention this as, notwithstanding the gentle warmth the mass of leaves may have imparted to the ground below them, I am far from certain that the fertile power of the ground is not impaired by its being denied the benefit of the winter's frost and constant contact with the air; but whether the Grapes inside would be quite so early or not is a question on which I have no hesitation in answering in the negative, and must therefore leave for others to say how much they are willing to sacrifice to attain such a result by adopting the more costly covering of glass, or something approaching it, and a more gradual exposure to the atmosphere in early spring. In our case we seldom take the leaves off until the first or second week in April, and invariably let the ground dry a day or two before it is slightly dug, and we expect the sun will supply the heat at that time which the leaves had been doing through the winter.

Having said so much on covering-up the borders of Grape houses intended for early fruit, I fear I must curtail what ought to be said on covers for those who endeavour to keep them late. I am the more anxious in this to hear the opinions of others, as I confess at once of never having practised it; but it is possibly the more important of the two, only in this case I should say that a perfect shutting-off the rain was necessary, and furthermore that covering-up with dry leaves, fern, straw, and such things are not sufficient here, as the present autumn has given some lessons that way which I daresay many readers have learned to their cost. But in my case I may say that I never knew Black Hamburgh Grapes keep so badly as they have done this autumn; they ripened well, were fleshy, coloured well, and not at all thin-skinned, and certainly not watery. Well, we all know that September was on the whole a fine month, and the rain not remarkable until after the middle of October, long before which the Grapes had been duly ripened; but being required to hang, it soon became perceptible that the moisture the border was receiving was communicated through the system to the fruit, which swelled I believe, and the juice was forced through the skin and decay set in. Such is my opinion, and if it has been noticed by others possibly some inference may be drawn that may be useful another time. The season, I need hardly say, has been a moist one, but not more so than some others in which our Grapes have kept tolerably well, and the time decay set in was

sooner than it has been customary for us to cut them and put them in bottles; but I attribute their defective keeping to the lack of water I imagine they suffered from in July and August: hence a sort of premature ripening, or rather a ripening-off, before they had attained the full size they might have done if moisture had been more plentifully supplied to their roots; this, unfortunately, we had not the means of giving at the time, and the recent experience of those producing remarkably fine Grapes point to the conclusion that water if of the suitable kind can hardly be given in too large quantities at that time if the border be properly made. But I do not remember of ever noticing Grapes in so promising a condition go off so rapidly from the causes stated above or some other of a likely kind. Whether this could have been averted by an outside covering or not is a matter open to opinion, my own being that it could; but of this I would like to have that of others, more especially of those who have lost Grapes by the late damp weather, and if anyone has had experience of the beneficial effects of an outer covering as tending to preserve their fruit well, then so much the better; as amongst the opinions then given something useful will most likely be forthcoming, and the more likely to be so if those having been unfortunate would record their misfortune as freely as they do their successes, the one affording as much instruction as the other, and in many instances more.—J. ROBSON.

### CARNATIONS IN WINTER.

THERE has been already much written on the subject of growing winter-flowering Carnations; but as I have been tolerably successful in their culture for several years, and as my practice differs in some of its details from that of your other correspondents, I may be permitted to say a few words on the subject.

There is an idea in many minds that Perpetual Carnations are difficult to propagate, and that when propagated they are difficult to grow, and that after all they only supply a few odd flowers for cutting. This is not in accordance with my experience. Managed rightly they strike as freely as *Verbenas*, grow luxuriantly, and produce plants in nine months such as might be called specimens. The only secret in their cultivation is that they must never receive a check so as to be at all stunted. From the time they are put in as cuttings till they are in full flower they must be kept steadily moving. Let them stand about in small pots for three or four months, and they will never afterwards be worth their room.

February is the best time to strike them if they are intended for large plants, but they may with advantage be struck later if only small plants are wanted. There are numerous little side-shoots formed all the way up the flower-stem; these when they are  $1\frac{1}{2}$  or 2 inches in length should be pulled away from the stem with the finger and thumb; generally it will be necessary to pull the leaf at their base off with them, as they can be split away better by doing so. Sometimes they will be fit for inserting without using the knife at all; but if the bottom of the slip is at all ragged it should be cut even and then inserted firmly into light loamy soil. Those who prefer to use sand may do so at this stage; it will do no harm, but it is not necessary. Water heavily so as to settle the soil very firmly about the cuttings, and then cover with glass. The glass should not be removed even for a minute till the cuttings are rooted, which in an average temperature of  $60^{\circ}$  will take about a fortnight. They must then be very gradually hardened by leaving at first a very small opening while there is no air on the house, shutting up closely when the house is ventilated. In about three weeks or a month from the time of inserting, the glass may be removed altogether.

The simplest kind of propagating-box I know, and which I use extensively, is like those used by many people for growing *Geraniums* but deeper, and is covered by laying a pane of glass on the top. As soon as the cuttings have fairly commenced to grow they should be potted singly in 4-inch pots and kept in warmth for a few days till they recover, when they may be placed in a close cold frame or one with a slight bottom heat, and gradually hardened till by the middle of May, when they will do without any more protection. As soon as possible after this time they should be potted in their flowering pots, the fast-growing kinds into 10 or 12-inch, and others of less robust habit into pots of 8 inches diameter.

The soil used is simply a light fibry loam and charcoal. No manure either liquid or solid is ever given them. I do not think they like it. By the end of September they will have

grown into large plants and be well furnished with flower-buds. It will be necessary to house them before the least frost touches them, for they are not at all hardy. A light airy house is the place for them, with a temperature through winter not lower than 50°. They will do in a much higher temperature and the flowers will then open quicker, but the colours will not be so good and the plants will not last in condition so long. For supporting the flowers I stick birch twigs amongst and around the plants when growing; these keep them up well and do not look so stiff and formal as stakes. I only keep the plants one season, as they never look so fresh and healthy afterwards.

The kind which I have found to be the most useful is a bright red one called Belle Rose. It produces its flowers abundantly all through the winter. Purity is the best white I know, and it is highly scented. A good red-and-white-striped kind is Beauty; and Miss Jolliffe is a beautiful pink, very free-flowering, and very sweetly scented. This last differs in habit from other Perpetual Carnations. It grows more like a Pink, and an 8-inch pot is large enough for it.

Green fly is the greatest enemy winter Carnations have, and a sharp look-out should be kept for it; for if it once gains a footing it has such a chance of hiding itself from fumigating and washing that it is extremely difficult to eradicate.—WILLIAM TAYLOR.

### NOTES BY THE WAY.

OROYDON.

ONE is sometimes reminded by a trivial circumstance of the lapse of time; and when the other day I shared the hospitality of my friend the Visar of Oroydon, I could hardly believe what on comparing notes I found must be true, that it was twenty years since last I had done so. How many thoughts crowded upon our mind, and what eventful years they had been in our own personal history and in that of our nation. How much, too, had taken place in that little world of horticulture in which we were both interested, and how much there was to talk about on matters connected with some of its special subjects. It was not a time very suggestive of pleasant thoughts in relation to gardening. Heavy floods, cold winds, and the promise of a sharp frost are not kindly reminders of the joys that horticulturists delight in, yet at all times one can find something to talk about and something to see; and it may interest some of our friends to read a few notes on what I saw that dull November day in the semi-urban and semi-rural town of Oroydon.

THE VICARAGE.—Situated as it is just outside the town on the Waddon side, and protected by fields which Mr. Hodgson has in his own hands, from being outbuilt, one finds in the surroundings of my good friend a veritable *multum in parvo*. Time was when he was celebrated for his breed of Cochins, but his love for the garden has overcome that for the poultry yard; and although he still keeps fowls, yet clearly they have given way to the flowers and fruits; and anyone who wishes to see what can be done in a small place by one who has a willing heart could find no better place to gain a lesson than this vicarage garden. There is for the size of it a pretty considerable quantity of glass, and the structures are used for all purposes. Thus, there is a small stove, on the roof of which *Allamandas* and *Passiflora quadrangularis* were giving even then their brilliant and curious blooms; while beneath were plants of various families—Ferns, *Gloxinias*, &c., which are useful for house decoration, and are in themselves beautiful and interesting. Then there is an orchard house, in which Peaches and Nectarines had afforded a fine supply of good fruits; vineries, where the Grapes had indeed been gathered, but where the Vines—and many of them the newer and rarer sorts—gave evidence of health and vigour. And then there was the nattiest little fruit house that can possibly be imagined, the one thing about the place which made me in danger of breaking the tenth commandment. The garden itself showed the same taste for all things worth having. Strawberries were very fine, and Dr. Hogg was looked upon as about the best. Magnificent fruit is gathered from it every year, and the beds looked most healthy and promising. Roses, too, were fine, and here as elsewhere I found the seedling Briar highly spoken of, and it seems likely to become a very popular and useful stock. The Pear and Apple, pyramids and bushes, were in excellent order. Fine samples of that grand November Pear *Doyenné du Comice* were in excellent eating order, and the fruit room displayed a goodly number of Pears and Apples

gathered from these trees ready for future use. Lilies, too, came in for their share of attention, and seemed from the flower stalks I saw to have done very well. Then Mr. Hodgson is a devoted lover of the *Gladiolus*. He has been an exhibitor and exhibited well and successfully, and it was a pleasant thing to talk over the flowers we had grown and compare our notes together. I fear that while, like many, he has to deplore the disease amongst his bulbs, he does not believe in the degenerating theory. There are some kinds more difficult to keep free from disease than others, but they are not those which are higher bred than many which we can keep free from it, while also it makes its appearance immediately on seedlings which have never bloomed. A new site has been selected for the beds this year, and I should imagine that they will be likely to do well.

WADDON HOUSE.—The name of Mr. Philip Crowley is well known amongst the horticulturists of the metropolis; and those who have known him will not be surprised, I imagine, to hear that his place is brimfull of valuable and rare plants. It is one of those old manor houses which were at one time so abundant in the neighbourhood of our great city, but which are being gradually improved off the face of the earth. I could see that the place itself with its well-kept lawn and good shrubberies would be worth seeing. As it was, I had to content myself with going through the houses. Adjoining the mansion is a very handsome conservatory, over the roof of which rambled in wild profusion the lovely *Tacsonia Van-Volxemi*, for ever blooming, and then full of its beautiful crimson parachutes hanging down all over the house—the very perfection of conservatory climbers. The conservatory is terminated by a fernery, the floor of which slants so as to give the idea of a natural cavern, and is composed of large flat stones, such as one might expect to see on the Devonshire coast. It is heated; and the Ferns, with here and there a *Begonia* intermixed, seemed to luxuriate in their abode. The range of glass is extensive, and both in stove and greenhouse were to be seen many of the plants which have been introduced of late years, all of them seeming to be well cared for and in fine health. An orchard house was in course of erection, while the Vines were evidently in sound health.

I regretted that Mr. Crowley himself was absent and that my time was so hurried, or I might have been able to glean something more worthy of notice; but if any of the readers of the *Journal* should, during the course of next year, be visiting Oroydon and be really interested in horticulture, they would find in both of these places a good deal to interest them, and I am sure would meet with a kindly reception from both Mr. Hodgson and Mr. Crowley. There is no greater pleasure in horticulture than to go over one's garden with anyone who thoroughly loves the pursuit, while those who only come to pass away the time are a great bore and may easily be bowed out after a short visit.—D., Deal.

### PEACHES AND NECTARINES.

DIAMOND (more properly Dymond) was raised by Messrs. Veitch of Exeter. I do not possess it.

"A. W." (page 484) asks if anyone can recommend a later Peach than *Noblesse* that will ripen in the midland counties. I recommend for that purpose *Barrington* and *Rivers' Nectarine* Peach. Mine is a very cold and exposed garden, and they will ripen here. Lord Palmerston and the Princess of Wales require to be gathered and placed a few days under glass; then pare them, slice them, and eat them with sugar. So used they are good.

A good selection of Peaches would be *Early Louise*, *Early York* or *Early Alfred*, *Dr. Hogg*, *Early Ascot*, *Grosse Mignonne*, *Royal George*, *Noblesse*, *Bellegarde*, *Barrington*, and *Nectarine* Peach.

A good selection of Nectarines would be *Lord Napier*, *Elruge*, *Downton*, *Violette Hâtive*, *Rivers' White*, *Emmerton's White* (later than the previous one), *Rivers' Orange*, *Pitmaston Orange*, and *Pine Apple* to finish with it.

If "A. W." would put some chalk or lime into his soil it would greatly improve it. Stone fruit like chalk and lime.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

STELLARIA GRAMINEA AUREA.—In reply to "ONWARDS" I have grown *Stellaria graminea aurea* this season for the first time, and am highly pleased with it as a carpet bedding plant, and for that purpose it will undoubtedly supersede the Golden

Feather. It is excellent for making the ground colour of carpet beds. It is easily propagated, grows freely, and is quite hardy. But I would prefer Golden Feather where it has to be used along with Geraniums, Verbenas, &c., in ordinary flower beds and borders.—B. INGLIS.

### PLANTS FOR CUT FLOWERS AND SPRAYS.

**CYCLAMENS.**—The beautiful and varied colours of these flowers and their delicate perfume entitles them to a place amongst the choicest of cut flowers. They keep fresh in water as long as any other flower, and are very suitable for button-hole bouquets. Well-grown plants are also admirable for dinner-table decoration. These may be regarded as everyday decorative plants of the first order of merit.

The Cyclamen season may be said to commence with *C. europæum album*, white and sweet, which flowers in September or earlier, the variety *rubrum* being a pale rosy pink with richly marbled foliage, and is probably the species *europæum*. *C. hederifolium*, rosy pink, flowers in September, with its white variety (*album*) is very beautiful. The bulbs of these are very large. I have seen naturalised roots nearly a foot across and producing over two hundred flowers each, and these are followed by the leaves, which are usually about half as numerous as the flowers, and are beautiful all through the winter. *C. græcum* is certainly very much akin to *C. hederifolium*, the flowers rose and white, and the foliage grand. *C. africanum*, bluish or flesh purple tips, is also of near kinship with *C. hederifolium*, but larger in all its parts. *C. nobile* is of the same class with *C. hederifolium*, they all flowering in autumn, and have splendid leaves. Except perhaps the two last all are hardy, and succeed in light rich loam enriched with leaf soil, doing well in well-drained borders, the ledges of rockwork, and in woods, where they are quite charming in autumn from their flowers, and in winter and spring by their leaves. The corms are most vigour when covered by decaying leaves, in the debris of which the plants appear to luxuriate, doing equally well in the most shaded as in the open parts. I doubt not but they would thrive in a light well-drained soil in most parts of this country, and what a charm they would give to the woodlands and rural walks when the trees are assuming autumn tints.

*C. neapolitanum*, red, flowers in early November and before the leaves, and is followed by *C. coum*, deep purplish red, which I have had blooming on rockwork early in December; also *C. coum vernum*, which usually flowers in February, and differs only in that and in having variegated foliage. *C. Atkinsoni* or *ibericum* with the varieties *album*, white with purple centre, *roseum*, rosy red, and *rubrum purpureum*, deep purple red, also flower early in winter, or on the first return of spring, and are all hardy, doing well on the ledges of rockwork; but to have their flowers during the winter months they require to be grown in pots or pans, placing their corms about their diameter apart, and covering them with soil about an inch deep. They do well in a light position in a house from which frost is excluded. Outdoors they require rather shady positions, and appear to thrive best on the limestone formation. *C. coum* and *C. ibericum* (*Atkinsoni*) flower with the leaves. After flowering under glass the plants may be placed in a cold frame, and in summer be kept in a slightly shaded position. Rich loam, with some leaf soil, and a little sandy peat with some pieces of chalk or old mortar rubbish, three parts loam to one part each the last three, with good drainage, will grow them well. They like watering overhead when in free growth.

*C. hederifolium* or *repandum* is a bright shaded deep rose colour, but varying, and flowers during early April. It also likes limestone, and to be shaded not densely in summer, and to be well drained. All the hardy Cyclamens are impatient of dry cutting winds, and should therefore have the shelter of a projecting rock in rockwork or other shelter of a wind-breaking character.

*C. persicum* is now pretty numerous in variety, and many have finely variegated or marbled leaves, which render them very effective for decorative purposes. They are easily raised from seed; plants so raised and grown-on in heat flowering within the twelvemonth from sowing. Grown in a warm greenhouse and starting early in August plants may be had in bloom by December, and to bloom well during the early winter months they require a temperature of 50° from fire heat, and ordinarily in a greenhouse the flowering will commence in February and be continued up to May. Their treatment has been so frequently given in this Journal, and is treated of in

the "Greenhouse Manual," so that I need not give any lengthened cultural hints.

**SOILLA.**—*S. bifolia* is the first to bloom, followed by *S. siberica*, both bright blue, and both do well in pots, potted in September, and brought forward in a cool house in an airy position after October. In a greenhouse they will flower by January. Of *S. bifolia* there is white (*alba*), *carnea* (red), and *rosea* (rose) varieties, all pretty. *S. amœna* is a purplish blue, and follows *S. siberica*. *S. campanulata* is light blue, and has white (*alba*) and rose (*carnea*) varieties, which flower in May or earlier, and grown in pots and forwarded as Hyacinths they flower in March or early in April. Their tall spikes of pendant bell-shaped flowers are very useful and effective. *S. autumnalis*, purplish blue, flowers in August or early September. Greenhouse or cool-house kinds are *S. peruviana*, with its corymb of blue flowers with yellow stamens. Its white and yellow varieties, with *S. ciliaris* (mauve), *S. corsica* (white), and *S. Hughii* (light blue) are all in the style of *S. peruviana*, and flower in early summer, whilst *S. japonica*, white with rosy purple, flowers in August or early September.

Squills in pots require light airy positions, a free sandy fibrous loam, with a third of leaf soil and a little sandy peat, the bulbs to be covered, and the pots to be well drained; have the diameter of the bulbs between each, and half their diameter from the sides of the pots; but some have large bulbs, as *S. corsica*, and they may be grown singly in pots twice the diameter of the bulbs. Outdoors the hardy kinds may be planted 3 inches deep in sandy soil well drained.

**BEGONIAS.**—The bulbous kinds flower from May throughout the summer; they are grown in the stove, greenhouse, and outdoors, in which latter case they require to be started in gentle heat and planted-out after the middle of June. The old *B. Evansiana* (discolor) may be mentioned as a good window plant with pinkish flowers, and is useful for our purpose, as its flowers have fragrance. *B. waltoniensis*, pink flowers of a waxy texture, the bright shining shaded green of its leaves and its crimson stems render it a fine window plant, and cut along with its leaves or as sprays is very useful for bouquets, &c. It is very accommodating, blooming continuously in a stove, and it does well as a greenhouse plant when kept dry in winter, and outdoors in summer it is, very effective.

*B. Veitchii* has large flowers of a vivid vermilion cinnabar red, 2 to 2½ inches across, and is sweet-scented. It is equally accommodating as *C. waltoniensis*; stove, greenhouse, window, or outdoors suits it.

*B. Pearcei* has yellow flowers, with leaves of a dark velvety green with lighter veins, and is very elegant, and of this there is some effective seedlings. I have no experience of it beyond a cool stove.

*B. intermedia*, vermilion red, flourishing in a greenhouse; also *B. roseiflora*, large flowers, carmine red; and *B. Richardsiana*, with elegantly cut leaves and white flowers like *B. Dregelii*, which last is very useful for cutting and does in a greenhouse, blooming in a stove all the year, it and *B. waltoniensis* being most useful.

*B. cheloni* has large salmony orange flowers, drooping, and flowers grandly during the winter in a cool stove. *B. Martiana* (*diversifolia*) is a fine subject for winter-flowering in a cool stove, and does well in a greenhouse; the flowers are rich rosy cerise, very abundantly produced.

*B. boliviensis*, glossy red, and its several varieties, which as cool-stove plants flower in early summer; and kept cool and dry up to April, and then started in gentle heat, do in a greenhouse, or may be planted-out in June in a warm sheltered position outdoors, and they will flower freely.

*B. semperflorens*, white or bluish flowers, is very dwarf and very free-flowering, with shining green leaves; it is desirable as a table plant. It flowers in a cool stove from January to May. The tuberous-rooted Begonias, of which there are many fine varieties, are especially suited for greenhouse culture when the summer occupants are outdoors, requiring only to be started in heat and removed to the house in June, and of late years in sunny positions outdoors they have been used with good effect. Planted on rockwork it is likely that many kinds will prove hardy. They require to be fresh potted when starting or required starting into growth, to be moderately watered until in free growth, then freely, but never soddened, and when the flowering is past reduce the water, withholding altogether when the plants die down, and store away in the pots in any dry place safe from frost. A compost of three parts turfy loam, one part leaf soil, half a part each old cow dung and silver

sand, with good drainage will grow them finely. Moderate pot room only is required.

Though the flowers of Begonias are not very durable, and are of the worst for travelling, they are very effective whilst they last in a cut state; and those with bright green leaves, as *weltoniensis* and *Dregal*, superb when used as sprays, which are desirable even without the flowers.—G. ABBEY.

#### APPLYING CARRION TO VINE BORDERS.

WITH reference to what has appeared in your pages lately regarding carrion, &c., as applied to Vine borders. All who have given an opinion on the subject are agreed that carrion or blood in a fresh state acts injuriously on the constitution of the Vine to which it is applied. There is not the slightest doubt, however, that the Vine is a very gross feeder, and when furnished with plenty of sound fibry roots it would be difficult to err in the matter of strong feeding, as an evidence of which I will record the case of two vineries in one of the northern counties of England. One of these vineries (when I knew them) was a Muscat, the other a Black Hamburgh house. The Muscat house was the admiration of all who saw it, the bunches being of immense size, well finished, and carried off first honours invariably wherever they were exhibited. The Hamburgh house gave good fruit of fair average size and quality, but certainly not to be compared to the other, which was a little remarkable seeing that both houses received the same treatment, the borders were made up of the same material, and so far as the casual observer could discern both houses were on an equal footing. Such, however, was not the case, as was afterwards discovered.

The main sewer from the mansion was carried down by where the vineries stood. It went straight along the front of the Muscat house border, but diverged off before touching on the Black Hamburgh border. After the lapse of years the sewage from the mansion would not pass away, when it was determined to start at the hall, open up the sewer (which was built of brick and stone cover), and follow on until they found out where the stoppage was. They reached the Muscat vinery. Here was found out the secret of the stoppage. The Vine roots had found their way through the brickwork, and the sewer was fairly choke full of clean, healthy Vine roots wallowing in the sewage accumulation of years. Herein, then, lay the secret of the almost unexampled success that had attended the cultivation of what is considered the most difficult class of Grapes to grow and finish properly; and I am pretty confident before this occurrence that the cause of their very superior well-being was unknown even to those in charge.

From such circumstances as these it is apparent that to grow Grapes of the very highest excellence the Vines must be liberally supplied with strong food. Other Vines also I have in my mind's eye, that have been a good deal heard about, are annually treated to a top-dressing of something akin to the sewer in question—namely, carcasses of dead animals decomposed and mixed with other ingredients in the form of soil, charcoal, &c., and there is not a doubt that such stimulants in one form or other play a very important part in the production of the enormous bunches that have been produced of late; but before attempting to use such strong stimulants it is necessary to have a well-drained and prepared border. Vines in vigorous health, which of course means good root-action, will be greatly benefited by such applications, but certainly not by burying carrion in bulk in a raw state.—J. B. S.

#### OUR BORDER FLOWERS—HYDRANGEAS.

If we cannot class Hydrangeas among our herbaceous plants we can afford them space in our beds and borders. They can be turned to good account both for in and out-door decoration. There was a time when many experiments were tried to produce blue Hydrangeas, but I can only entertain the idea that it is one of those unaccountable freaks that Dame Nature treats us to sometimes. I am not aware that there is any fixed law as to the sport remaining permanent; but, be that as it may, blue Hydrangeas are very desirable when they can be had. Hydrangeas will live through the winter in favoured localities. More than thirty years ago I remember seeing in Dr. Herbert's garden at Spofforth a plant of *Hydrangea hortensis* 8 feet high and as much through, that had been planted out many years; this plant had a framework of wood placed round it, the branches drawn together, the framework being filled with dry leaves, and all thatched over with

clean straw; and the plant was worthy of that protective care, for to see it loaded with its huge bundles of beautiful pink flowers during the autumn was worth going a day's journey to see.

Hydrangeas grow well in good sandy loam, peat, a little well-rotted dung, a sprinkling of chopped bones and lime rubbish mixed well together. It is a long time since *Hydrangea Hortensis* found its home among us, and plants of it are still highly prized among many of our rural families, and in some instances are looked upon as heirlooms. They are easily increased by cuttings from half-ripened shoots cut at a joint and inserted in sandy soil in heat, and also by division when they are beginning to make young growth. The variegated kind I find to be a useful plant for edging large beds with, and equally useful for indoor work. It is a pity that we have not a golden sport to vie with the one we have. The plants can be lifted from the ground in the autumn, and stored in boxes with sufficient soil to keep them alive through the winter. In the spring they may be divided and potted if required. I am inclined to think that there might be prizes given at cottagers' shows for encouraging the growth of these effective window and border plants, for they are not cultivated nearly to the extent they ought to be.—VERITAS.

#### GERANIUMS FOR WINTER FLOWERING.

I now leave to call the attention of those of your gardening readers who may not be aware of the great usefulness of Geraniums for autumn and early winter flowering to the above fact. The conservatory here has been moderately bright and cheerful-looking up to the present time, and we hope will be so for some time to come, with a small collection of these. We have used them for two or three seasons past, and have been fortunate in having Geranium trusses more or less to cut at any time during the winter season. The dark-coloured varieties we have found the most useful in all respects, the colours being deeper at this season, the flowers standing better and being more appreciated by the ladies than the light varieties. If we were restricted to one particular sort our choice would fall on *Diana*, a dark crimson free-flowering variety, which ought to be pretty well known by this time. I have seen and had to do with most of Dr. Denny's seedlings, and like this one best of all; nor have we ever come across anyone who did not take to it directly. It should be grown in quantity wherever there are flowering plants grown. *Jessica*, another of Dr. Denny's raising, is also very fine just now, and is decidedly an improvement on *Wellington* for flowering at this season. As a rule the above strain of Geraniums are to be depended on for winter blooming. *Fred George*, a splendid sort when it does do well, is in fine order just now, only it is not to be depended on as a rule; but for summer flowering it deserves to be more cultivated. *Don Giovanni* seems likely to excel as a winter-flowering sort. There is a dash of purple in it that deepens in shade considerably at this season, making it all the more effective. *Princess of Wales*, a rosy scarlet flower, is also promising well. *H. M. Stanley*, an exceedingly floriferous variety considering the size of the trusses, and crimson in colour, is first-rate. *Henry King*, *Jean Saisley*, *Vesuvius*, are also to be depended on in the scarlet-flowered section. I had almost forgot to mention *Excellent*, which is well worth growing for the above purpose. Of pinks there are none to beat *Master Christine*; as a rule I have always found it a perpetual bloomer, and it is in all respects one of the most useful sorts in cultivation for pot culture. We find *Metalf* do very well at this season, and it deserves growing in quantity. *Blue Bell* is finer-flowered at this season than at any other, the blue being more distinct—a trait of all sorts in which a shade of blue is apparent. The newer varieties with large flower-trusses are not so useful for late work as the smaller-trussed sorts; but by having the flowers developed by the beginning to the middle of September, these can be kept in presentable order for ten weeks or more. *Polly King* is the best of the sorts with a shade of salmon in the flowers that we have tried; it is fairly floriferous, and well worth growing. For summer flowering it stands as one of the best. *President Thiers*, an attractive self-salmon flower, was fine up to the end of October, but does not seem adapted for a winter flowerer. Amongst whites we like the old *White Perfection* as well as any. *White Clipper* is, if not identical with the last, very much like it. *Florence Fraser* is a very pure free-flowering variety, the purest white we have, but does not do so well at this season as the first-named. We have a number of other

sorts, but these are the ones which have succeeded best. All others we have tried do well up to the end of October; but the buds never open after that time, consequently they are worthless for winter.

With regard to the best means of preparing the plants to flower now, were we to commence with a set of young plants we should prefer autumn-struck cuttings, kept growing gently during the winter in 8-inch pots, transferred in spring into others not exceeding 6 inches in diameter, using a sandy loam and potting very firmly. As soon as possible the plants should be placed out of doors; and when under glass, so long as they are kept moving, the hardier they are kept the better. We had ours half-plunged in a south border this summer. Beyond keeping supplied with water, the flower-trusses being picked off, and any rank-growing shoots stopped, with a little stimulant occasionally, nothing more is necessary. They should be kept out as late as possible, so long as the flowers are not destroyed by rain or frost; the longer they can be kept out the better. When they are staged in the conservatory the one great point is to keep them free from the effects of damp. We are quite as careful with them in this respect as we are with late-keeping Grapes. If the weather is dull, cold, or rainy a gentle heat should be kept up in the pipes or flues. Just now we have a small fire burning constantly. So long as other plants are not unduly excited it does such things as Cyclamens and Chinese Primroses good, whilst a few Fuchsias may be kept blooming well into winter. Indeed, when a supply of flowers has to be kept continually in these structures it is impossible to do so satisfactorily at this season without the aid of artificial heat pretty constantly being called in. It does not do to keep the plants too dry—they do not require so much water in comparison as they do when growing—but when a certain stage of dryness at root is passed and no water given the plants suffer and the flowers wither. Summer-flowering plants if well treated do quite well for winter flowering. Last year we had them in flower in the conservatory up to the end of August, when they were required there no longer, and had the same plants full of bloom at the beginning of November. Plants may be also transferred to mixed borders during the summer, and lifted in autumn when there is a good set of flower buds, potting into the smallest-sized pot possible. As a rule, however, we like one-year-old plants in small pots.—R. P. B. (in *The Gardener*).

#### PEAR BESI VAET.

I THINK it desirable to call especial attention to a Pear that is a stranger to many fruit-growers, and also because some of those who are acquainted with it have an erroneous impression that it will not ripen in this country. Ample proof of how little it is known or valued is lying beside me as I write, in the form of fifteen fruit catalogues received from as many different nurserymen, and it is found in only two of them.

A flourishing young tree of it, a pyramid on the Quince, had some fine fruit this year which was gathered and stored in the fruit room October 12th. Knowing that its fruit was thought worthless, or at any rate only suitable for stewing, by some of those who had given it a trial, I was induced to put one or two upon a shelf near the office fire, and upon tasting one on November 18th I found it to be perfectly delicious—sweet, juicy, and rich, with a slight yet most agreeable acidity, somewhat resembling the Chaumontel, but decidedly superior even to Jersey-grown fruit of that variety; and I have no hesitation in strongly recommending it as a dessert fruit of the highest excellence.

I need hardly add that as soon as I became aware of its great value the whole of the fruit was taken into the same genial temperature in which the first fruit was ripened, and which is about equal to that of an ordinary dwelling-room.—EDWARD LUCKHURST.

#### ROSE CLOTH OF GOLD.

It may interest those of your readers who are Rose-growers to know that there is a Cloth of Gold Rose at The Firs, Budeleigh Salterton, the seaside villa of Dr. Orompton of Manchester, covering a south wall 65 feet in length and 12 feet high. The girth of the wood where it is grafted is 7 inches. Last spring more than four hundred flowers were counted on it at one time. The shoots run along a cob wall thatched so as to prevent drip. The situation is sheltered, at the bottom of a sloping garden. The soil is a black loam, the subsoil

gravely boulders. The plant has been manured with bullock's blood. It was planted about twenty-seven years ago.—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross*.

#### POTATOES AT THE BIRMINGHAM CATTLE SHOW.

LAST year there were 153 dishes staged, and that was considered a very satisfactory show. This year there were 320 dishes, which constituted a much more satisfactory show, for not only is it numerically greater than previously, but the sorts exhibited are better, and, as we shall show further on, they yield information of greater value to planters.

Class 16 is a repetition with variations of a last year's prize. Mr. George Wise, a member of the Council, who has always shown a most lively interest in the welfare of the Society, and in a variety of ways has done the utmost in his power to encourage a sensible cultivation of Potatoes, offered a silver cup value £5 5s. for twelve tubers of each of the following eight varieties—viz., Ashleaf, Breese's Peerless, Dalmahoy, Fluke, Red Regent, Hundredfold Fluke, Paterson's Victoria, and Scotch Blue. He stipulated that unless there were five competitors the cup should not be awarded except on the special recommendation of the Judges. There were only four entries, and one of these was not staged, consequently only three competed. These are all fairly good, and one—that of Messrs. G. & J. Perry, Acton Pigott, Condover, Salop—was so good (with perhaps, the exception of Scotch Blue, which the exhibitors call Lyall's Scotch Blue—certainly not in any way resembling Scotch Blue as shown by the donor of the prize or like any other specimen of Scotch Blue in the Exhibition), that the Judges recommended the cup should be awarded to those gentlemen. We have not heard whether Mr. Wise has given his consent, and of course, under the circumstances, it cannot be awarded without.

In Class 17 a silver cup value £5 5s. was offered by Messrs. Sutton & Sons, the Queen's seedsmen, Royal Berkshire Seed Establishment, Reading, for the best six varieties, of which two must be the New Hundredfold Fluke and the Red-skinned Flourball—two excellent varieties introduced by that enterprising firm, and which from the prominence they justly take in this show, if from no other reason, they may be justly proud, for they are shown by many exhibitors not only in this class but in others, and by nearly all satisfactorily. The Judges report that the exhibits in this class were exceptionally good. There were six exhibitors. The winner of the prize (a handsome cup) is Mr. P. McKinlay, Woodbine House, Beckingham, Kent, who, in addition to the stipulated kinds, showed Barly Dimmick, Non-such, Snowflake, and Salmon Kidney—a very satisfactory and well-grown collection. In Class 18 Messrs. James Carter & Co., the Queen's seedsmen, 287 & 288, High Holborn, London, offered a silver cup value £5 5s. for the best collection of eight varieties, four to be English and four American, one of the latter to be the new American variety Breadfruit. The cup was awarded to Mr. Peter McKinlay, who staged the following:—Yorkshire Hero, Hundredfold Fluke, Main Crop, Excelsior Kidney (large, fine, and handsome), Late Rose, Vermont Beauty, Snowflake, and Carter's Breadfruit. In the same class Mr. James Betteridge was so close to the winner of the cup that the Judges, having no second prize to award, gave the unusual distinction of "very highly commended."

Class 19 commences the Society's prizes. It is for twelve tubers of Ashleaf Kidneys, or any variety of that type of Potatoes. To outsiders it may seem strange to so state a class, but those who are familiar with Potato names know that there are many so-called varieties known by all sorts of names which are nothing but Ashleaf Kidneys. There were eight exhibitors in this class, the following being the sorts exhibited:—Lee's Hammersmith Kidney, Myatt's Prolific (two dishes), Harry (early), Ashleaf, Gloucestershire Kidney, Captain White's Early, and Rivers' Royal Ashleaf. His Grace the Duke of Portland, Clipstone Park, Mansfield, Notts, wins the first prize; Mr. Thomas P. Taylor, Lymm, Warrington, the second; and Mr. James Betteridge the third.

Class 20 includes all Potatoes of the Lapstone Kidney type. Here again the named sorts are many, but all resolvable to the recognised type. Sir F. Smythe, Bart., Acton Burnell, near Shrewsbury, was first with a fine sample of Lapstone pure and simple; Mr. William Finlay, The Gardens, Wroxton Abbey, Banbury, second with a duplicate exhibit; and Mr. James Betteridge third. The other varieties exhibited in this class were Flukes and King of Flukes.

In the next class, No. 21, Rector of Woodstock, a new variety of great excellence but of recent introduction, only one exhibit was staged by Mr. Peter McKinlay, to whom the first prize was awarded.

Class 22, for Regents or Dalmahoy. Here the prizemen were T. L. M. Cartwright, Esq., Melville House, Lady Bank, Fife, first for White Regents; and the Duke of Portland second for Dunbar Regents, and third for Red Regents.

Class 23, for Paterson's Victoria. Here Mr. Thomas P. Taylor, Lymm, Warrington, was first and second; and Mr. Samuel O. Pilgrim, The Outwoods, Hinckley, third.

Class 24, for Vermont Beauty or Brownell's Beauty. The first prize was won by Mr. McKinlay, and the second by Mr. Betteridge.

Class 25, Snowflake, or any other white-skinned American variety. Mr. McKinlay was first, and Messrs. Cocks Brothers second; Mr. James Betteridge's collection was highly commended. The varieties shown in this class were Snowflake, Bresee's Peerless, Bresee's Prolific, and Early Goodrich, the two first taking the honours.

Class 26, other white-skinned varieties, drew together Waterloo Kidney, Finland's Early, King of Potatoes, Webb's Surprise, Sutton's Berkshire Kidney, Edgote Kidney, and Red Bogs. The Duke of Portland won both prizes; the first with Webb's Surprise and the second with King of Potatoes.

Class 27, for other coloured-skinned varieties, Sir Frederick Smythe, Bart., Acton Burnell, near Shrewsbury, was first, and the Duke of Portland second, with Red Flukes. The other kinds shown in this class were Red-skinned Flourball, Extra Early Vermont, Salmon Kidney, Late Rose, and Bexton Hero.

Class 28, for three distinct varieties. The Duke of Portland was first with American Rose, Wood's Scarlet Prolific, and Bresee's Prolific; Mr. James Betteridge second with Red Fluke, Bresee's Prolific, and Bell & Thorpe's Model; and Mr. T. P. Taylor third with Flukes, Regents, and Red Bogs (query, Dalmauys by another name?).

In Class 29, for six distinct varieties, the first and second prizes were won by the Duke of Portland with Bresee's Prolific, Waterloo, Red Regents, Snowflake, King of Potatoes, and Red Flukes in one collection, and with Red-skinned Flourball, Climax, Waterloo, Main Crop, Hundredfold Fluke, and Bresee's Prolific in the other. Messrs. Cocks Brothers won third prize with Peerless, Snowflake, Brownell's Beauty, Bresee's Prolific, Climax, and an unnamed dish, probably American Early Rose.

Class 30, twelve distinct varieties. The Judges report that it was an extra good class. The prizes were awarded as under:—First and extra prize (silver cup value £5 5s. given by George Wise, Esq.), won by Messrs. G. & J. Perry for a very grand lot, including Red Regents, Carter's Ashleaf Fluke, Bell and Thorpe's Model, Harrison's Red Fluke, Wood's Scarlet Prolific, Snowflake, Sutton's Red-skinned Flourball, Bresee's Prolific, Sutton's American Pink Eye Busty Coats, Wheeler's Milky White, Perry's New Seedling, and Brownell's Beauty. Mr. McKinlay won the second prize with a high-class collection of medium-sized tubers, the sorts being Scotch Blue, Model, Johnson's Seedling, Early Gem, Late Rose, Snowflake, Early Dimmik, Salmon Kidney, Vermont Beauty, American Breadfruit, King of Potatoes, and Red Emperor. The third prize was won by the Duke of Portland.—(*Midland Counties Herald*.)

### GROS COLMAN GRAPE.

MR. DOUGLAS has alluded to the flavour of this Grape as being esteemed by many. I shall be glad to know if this is really the case, for I am compelled to say that I have never been able to pronounce it otherwise than of unpleasant flavour, and I have never heard anyone say that it is in any degree good. I have had the opportunity of testing it on exhibition tables, and have also tasted it off the Vine in several vineries in which I have seen it growing, but never yet have I considered it, except for its noble appearance, worthy of being placed on the dessert table. It is possible, however, that in certain soils and on some stocks that the flavour may be good, and if so it is very important that the conditions be made known, for in appearance it is the finest of all black Grapes. The Vine has also a vigorous constitution, and is a free bearer and good keeper.

Mr. Rivers has described it as possessing a "peculiar flavour," and as ripening its fruit in a cool vinery. I agree that its flavour is "peculiar," but I think it is a mistake to recommend any late Grape for a cool vinery. I have grown it in a cool vinery, but the fruit was positively nasty, and I have never found it even fairly good except when grown under Muscat treatment.

Dr. Hogg in the new edition of the "Fruit Manual," describes it as a magnificent Grape, the fruit being as large as some Plums, of a dark purple colour, but states that the flavour cannot be called either "rich or agreeable," and adds that it requires a "considerable amount of heat to ripen it." That is precisely my experience, as it is also that of many growers with whom I have discussed the merits of the variety.

As a considerable amount of experience has now been had with this splendid-looking Grape (for I find that it is fruiting in many vineries), it would be of great value if that experience

could be placed on record, and especially if the conditions could be stated by which it was esteemed by its flavour as a desirable addition to our present late Grapes. If it can really be produced of good quality it should find its way into all Grape-growing establishments.—*Ex-Exhibitor.*

### THE ROSE ELECTION.

SINCE the publication of the perfume poll I have received the following post card addressed to me—"Florist," an addition to my name to which I have not the slightest claim.

"I share your surprise about La France. Has not François Lacharme, most fragrant of Roses, been accidentally omitted from the list? It is far more deliciously scented than most of those named.—A ROSE DEVOTEE."

In reply to this, I may state that François Lacharme received only two votes. I share "A ROSE DEVOTEE's" surprise at the low position of this deliciously scented Rose; of the two votes one from the Blandford Nursery placing it A1, the other, my own, placing it in the second category. But as our good friend Mr. Curtis says, the matter is in its infancy; and if in a year a future returning officer for Roses should try a Perfume Election, I fancy the results will be somewhat different.—JOSEPH HINTON, Warminster.

### THE ROOT-PRODUCING POWER OF SAWDUST.

IN the cultivation of nearly all tender plants in common flower-pots, gardeners have frequently to deal with subjects that have got into bad health and decline, solely because the soil in which they have been potted has become what is generally termed "sour." It would be about as reasonable to expect a human being to thrive with his blood surcharged with bile as to expect a plant to thrive in a potful of soured soil; and some curative measures are always necessary if the plant is to live and thrive. The derangement is often caused by insufficient drainage, overpotting, and overwatering; and in the case of Pine Apple plants often from an unobserved continuous dripping of moisture into the pot.

The practice of restoring plants that are so deranged is to shake all the soil from the roots, wash them clean, prune away all decaying portions, and repot into a small pot in rather sandy and fresh soil, and when they attain good health shift them on in the usual way. This season we have experimented on some plants—a good many of which did not absolutely, and some which very much did, require restorative measures. The plants were shaken out and potted—not into very small pots for the sizes of plants—in pure fresh sawdust, and the rapidity with which in all cases the roots multiplied and gained strength has been such as we never witnessed in a long experience. Pine Apple plants produced such a mass of twiggly white rootlets as we never saw attached to a Pine plant before. The same may be said of Dracenas, Anthurium Scherzerianum, and other plants; and we shall certainly continue to use sawdust as a root-restorative for any plant that gets into bad condition at the root. They produce as many new roots in a few weeks in it as they do in soil in as many months; and when the roots are produced it is only necessary to shake them out of the sawdust cleanly, and pot into the soil which suits them. We should like our readers and correspondents to try this means with plants in bad condition at the roots, and report their experience. The sawdust we use is from a mill where all sorts of home-grown timber are sawn. We shook out a small Smooth Cayenne Pine a few days ago that had been allowed to remain for two months in the sawdust, and such was the network of roots that it was not possible to rid them of the sawdust without breaking up the ball. It had been allowed to remain too long in the sawdust for the object for which it is recommended.

On the Continent some nurserymen propagate largely in sawdust, and strike extra-sized cuttings far quicker than by any other means.—(*The Gardener*.)

TREES IN TOWNS.—The Corporation of Birmingham have made a commencement in tree-planting in their busy streets. The spot selected for the initiatory step is Stephenson Place in front of New Street Railway Station. Councillors Parry and Barker, the Town Clerk, the Borough Surveyor, Mr. E. W. Badger, and Mr. B. H. Vertegans who supplied the trees, with a few casual passers-by, were the only persons present. Two fine Occidental Planes were planted, and some hundreds of

similar trees will as speedily as possible be placed in various parts of the town. Long may they live and flourish.

### AURICULA CULTURE AT SHEFFIELD.

THE richest and healthiest collection of Auriculas that I know of among Sheffield growers is that of Mr. Simonite. They are grown in a low span-roof house. The only protection against the sooty air is that the ventilation is at the side and not overhead; and such a marvellous amount of dirt falls on the roof glass as to render much shading from the sun quite unnecessary. It is such smoked glass that the sun looks only like a great moon through it. My friend cleans his Auriculas from insects as I do with a small brush, and this is the only cleaning the foliage gets unless we have a plant much infested, and then it is dipped overhead in soft-soap water.

The plants I speak of at Sheffield are in grand health and wonderfully clean, but of course not so bright in the white meal and clear in the green as those are which have the benefit of sweet country air.—F. D. HORNER, *Kirkby Malzeard, Ripon.*

### NOTES AND GLEANINGS.

AN extraordinary abnormal specimen of the common POLYPODY (*Polypodium vulgare*), has been submitted to us by the Hon. and Rev. J. T. Boscawen. The fronds were gathered from a plant growing in a garden at Launceston. One of them had the pinna partly of the normal shape, the remainder being curiously crested and divided, but the other frond was totally dissimilar, and was in fact perfectly distinct from any example we have seen of this genus. So finely was it divided, so feathery, and apparently so perfect, that it resembled the *Hymenophyllum* rather than the *Polypodium*. No Fern, either native or tropical, could be more charmingly elegant than this remarkable example, and if the form should prove constant it cannot fail to be a valuable addition to our hardy Ferns.

Mrs. EVANS of The Ferns, Eynesbury, writes to say that she regrets not seeing the CHESHUNT HYBRID ROSE named among the fragrant varieties, as she thinks that for delicacy of perfume it stands unrivalled, and also adds for beauty of colour and continuance of bloom.

Messrs. SUTTON & Co's STAND at the Birmingham Club Cattle Show was very superior. The collections of seeds and roots were some of the finest ever exhibited. Occupying a conspicuous position in the Show was a magnificent display of forty handsome silver cups upwards of two hundred guineas in value. These, with medals and other valuable prizes, amounting in all to five hundred guineas, will be presented by Messrs. Sutton & Sons to various agricultural and horticultural societies during next year for the best specimens produced from their seeds.

Messrs. CARTER & Co.'s STAND at the Agricultural Hall is as good as it was at the Birmingham Show.

THE AURICULA (says "Nature") is said to be the only Alpine plant which has come into general cultivation in the gardens of the rest of Europe. In a pamphlet entitled "Die Geschichte der Aurikel," Professor Kerner traces the history of the discovery and cultivation of this plant from the time of L'Escluse (*Clusius*), who first transplanted this species and the hybrid *P. pubescens*, *Jacq.*, in 1582, from the Tyrolean Alps to Belgium. The latter species, and not the true *P. Auricula*, *L.*, which quickly disappeared from cultivation, is believed by Professor Kerner to be the real ancestor of the cultivated Auriculas of our gardens. The two were known at the time of *Clusius* under the names of "*Auricula-ursi* I." and "*Auricula-ursi* II.," from the supposed resemblance in the shape of the leaves to that of the ear of a bear. The hybrid *P. pubescens*, which had been lost from the German and Austrian Alps for nearly three centuries, was rediscovered by Professor Kerner in 1867 in a single locality in the Tyrol.

According to the "Journal of the Chemical Society," a German chemist, Herr Haberlandt, has published elaborate tables, showing the minimum and maximum degrees of temperature at which various seeds will germinate. Wheat, Barley, Bye, Oats, Buckwheat, Sugar Beets, Linseed, Poppy, Clove, Lucerne, Peas, Rape, Mustard, and others have their minimum below 4.75° cent. (40.5° Fah.) The minimum for Saintfoin, Pimpernel, Carrot, Cumin, Sunflower, Cat's-tail Grass, Sorghum saccharum, Sorghum vulgare, and Maize, is between 4.75° and

10.5° cent. (40° and 51° Fah.) The maximum limit for Oorlander and Marjoram is between 25° and 31.25° cent. (77° and 88.2° Fah.); for Wheat, Bye, Barley, English Ray Grass, Vetches, Horse Beans, Peas, Chick Peas, Mustard, Red Cabbage, late Kohl Rabi, Turnips, Radishes, Madder, Fennel, Carrots, Parsley, Linseed, Poppy, Tobacco, and Aniseed, between 31.25° and 37.5° cent. (88.2° and 99.5° Fah.); for Beans, Clover, Lucerne, Early Kohl Rabi, Buckwheat, Chicory, Sunflowers, Spurge, and some sorts of Cabbages, between 37.5° and 43.75° cent. (99.5° and 108.7° Fah.); and finally, for Maize, Sorghum vulgare, Turnip Radishes, Hemp, Teasel, Gourds, and Sweet Melons, between 41.2° and 50° cent. (106° and 122° Fah.) Other tables are appended showing the per-centage of seeds germinating at different temperatures, the number of hours elapsing before the rootlets reached a length of two millimetres (6-100 inch), and the average growth of the rootlets in two days of different temperatures. In all cases there is increased root-growth from 18.75° cent. (64° to 77° Fah.), and in nearly all a decrease from 31.25° to 37.5° cent. (88° and 99° Fah.).

### PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

*PROTHOPHALLUS BIVIRID.* *Nat. ord.*, Aroides. *Linn.*, Monocotyledon. *Polypandria*.—Native of Cochin-China. Flower dark green and reddish purple.—(*Bot. Mag.*, t. 6195.)

*FERULA (EURYANGUM) SUMBUL.* *Nat. ord.*, Umbelliferae. *Linn.*, Pentandria Digynia.—"The plant is a native of Turkestan, where it inhabits mountains east of Samarkand at an elevation of 3000 to 4000 feet. It was there discovered by the celebrated traveller Fedachenko in 1869, who sent roots to Moscow in 1871. According to Flückiger and Hanbury's admirable work the Sumbul plant here described—which is remarkable for the fetid, musky, and milky juice of its root—was introduced into Russia in 1835 as a substitute for musk and a remedy for cholera; thence it reached Germany in 1840 and England in 1850, where it was admitted into the pharmacopoeia in 1867. In commerce the root is imported in transverse slices 1 to 5 inches in diameter, with a dry papery bark, resinous inner surface, and spongy farinaceous central portion, which has a musky odour and bitter aromatic taste."—(*Ibid.*, t. 6196.)

*CROCUS VELUCHENSIS.* *Nat. ord.*, Iridaceae. *Linn.*, Triandria Monogynia.—"It was discovered by Signor Vriani whilst collecting for the late Dean Herbert on Mount Veluchi (Tymphrestus), near the northern border of Greece (not the Morea, as inadvertently stated by Herbert in his final monograph of the genus in the Journal of the Horticultural Society), and has since been found on the Parnassus range, and in the mountains of Thessaly, Thrace, and Transylvania. The abrupt white tip to the otherwise purple perianth-segments shown in the plant drawn in the "Botanical Register" is not a specific character. We have lately received from Col. Trevor Clarke a flower of *C. vernus* with perfectly similar coloration. *C. veluchensis* is still a very rare plant in cultivation."—(*Ibid.*, t. 6197.)

*CARICA CANDAMARCENSIS.* *Nat. ord.*, Passiflorae. *Linn.*, Dicoelia Decandria.—"The graceful little tree was raised from seeds sent from the Ecuadorian Andes by the late Professor Jameson of Quito to the late Mr. Hanbury, with whom it flowered in an open border at Clapham in 1874. A specimen received from him again both flowered and fruited abundantly at Kew during the past summer and autumn, in the open air, where it was stood out after being brought into bud in a greenhouse. According to Mr. Hanbury this is the species mentioned by Mr. Spruce in his and M. de Mello's very learned and interesting paper on the Papayaceae, published in the Journal of the Linnean Society quoted above, as the Chambi-buru, or common Carica, of the Ecuadorian Andes, where it is cultivated up to an elevation of 9000 feet for the sake of its edible fruit. Mr. Spruce adds that when he visited the mountain of Tunguragua in February, 1858, the ground was strewn with its ripe and rotting fruits, which were smaller and sweeter than that of the common Papaw, and were the favourite food of the bears that infest the forests of that mountain."—(*Ibid.*, t. 6198.)

*DENDROBIUM AMCENUM.* *Nat. ord.*, Orchidaceae. *Linn.*, Gynandria Monandria.—Flowers white tipped with purple. Native of Nepal and Sikkim. "Flowered by Mr. Bull, who received it from the Himalaya (probably Sikkim), where it was found at an elevation of 5000 feet. It flowered in June, 1874, in his nursery."—(*Ibid.*, t. 6199.)

*PLUM—Prince of Wales.*—"It appears to have been raised

from the Orleans some forty-five years ago by Mr. Chapman, a market gardener of Syon near Brentford, and on account of its bearing qualities it has in the interval become very widely distributed amongst the market-gardening community. The fruit is rather above the medium size and of roundish form inclining to oval, and having a distinct suture. The skin is a bright reddish purple or purplish pink dotted with yellow dots and covered thickly with an azure bloom, which produces a tint very difficult to reproduce in artificial colours, and of which our figure perhaps shows too little of the bloom. The flesh is rather coarse-grained, separating freely from the stone, yellowish in colour, with a sweet juice and brisk flavour. The fruit ripens at the end of August or the early part of September. The Prince of Wales is one of the best culinary Plums grown, and is besides regarded by Dr. Hogg as a second-rate dessert variety. Thompson says it may be used like the Orleans both for dessert and kitchen purposes. The tree is of vigorous growth; the young shoots long and covered with a smooth bark, in which respect it differs from the Orleans; and the leaves are oval with a crenated margin and smooth upper surface.

"The tree is very hardy in character and a most profuse bearer even while young, which is perhaps partly owing to the large foliage acting as a protection to the blossoms. The fruit usually hangs thickly all up the branches, which at an early age are well furnished with fruit-bearing spurs. Of late years the trees in the market gardens about London have suffered considerably from the dying-off of large branches, but the cause of this malady has not been ascertained. It may possibly be due to exhaustion owing to the excessive crops it produces."—(*Florist and Pomologist*, 3 s. viii., 253.)

#### PEACH FORCING.—No. 5.

**FERTILISING THE BLOSSOM.**—Shortly after the flowers are fully expanded the anthers will be carrying ripe yellow pollen, and the stigmas will be viscid. It is necessary that the pollen come in contact with the stigma of each flower, and its effect be complete upon the ovary. This primary cause of the fruit arriving at maturity is of paramount importance, for unless the seed be formed, and not only formed but perfected, it will not in the case of a Peach or Nectarine ripen; and though we may not ascertain how many pollen grains are needful for impregnating, we do know that by some agency or other the pollen must be made to act upon the stigma. Naturally insects, those with nectar-sipping pollen-gathering proclivities, the disturbance of the atmosphere by the wind, even gentle rains or dew, may and naturally do cause the distribution of the pollen, some of which perforce must be disposed upon the stigmas, and fecundation thereby be effected.

Natural agents, however, but little avail the Peach-forcer. Insects are drowsy in winter, and a hive of bees in a Peach house, valuable as the bees may be in February and onward, are little good in December or January, whilst light syringing converts the pollen into paste and destroys the viscidness of the stigmas. Lightly and sharply tapping the branches with the hand (for a stick bruises, whilst the hand does not), the trellis or stems of the trees will cause the pollen to be cast as so much golden dust, and this practised every day after the pollen is yellow until the petals drop in the middle of the forenoon, or after air has been admitted, will in most instances be effective. Instances, however, of non-setting occur after recourse has been had to the distribution of the pollen by the shaking process, which may arise from the flower, though perfect in every other manner, being defective in the anthers—sterile of pollen. It is difficult to account for a deficiency of the pollen substance, but I have noticed the deficiency to prevail most in those kinds having large flowers, as Early York, Early Grosse Mignonne, Grosse Mignonne, Noblesse, Early Alfred, Early Rivers, &c., whilst those with small flowers, as Royal George, Bellegarde, Violet Hâtive, Early Louise, Elruge, and Violet Hâtive Nectarine, are very productive of impregnating matter. It is well to note carefully the trees at the time of blossoming, and any defective in quality of pollen may be fertilised with the superabundancy collected from other trees.

The best aids to impregnation are a clear sky, a dry atmosphere, and a light breeze as will be generated by free air-giving consequent upon the sun's heat expanding the mercury, and this with lightly shaking the trees already mentioned is often sufficient (care being taken to prevent, by a little air left on at night, the atmosphere from becoming close and stagnant)

to secure a good set. The chances of having bright weather at the time of the blossoming are about evenly balanced, and should the weather be dull and wet or foggy, the necessity for artificial impregnation may arise, and in case of a deficiency of pollen is absolutely necessary. So convinced am I of its utility, that I always resort to the disposition of the pollen by a camel's-hair brush. It is best done with a rather loose and spreading one than one with the hair closely set, and bringing the brush crosswise the anthers the act of disturbing them will cause the pollen to be dispersed, some of which will be caught by the brush soon becoming coated beyond its power of retention with the golden dust, and as we draw the brush across the anthers the stigmas must hold some of the pollen.

The blossoms do not all attain full expansion at once, and the fitness for impregnation varies in different individuals; therefore, the trees should be gone over frequently, and only those having ripe pollen should have the brush drawn across them. Any trees with deficient pollen may be gone over with the brush after using it upon those with abundance of pollen, and whilst those are being done a sheet of white paper held in the left hand whilst the brush is employed with the right, and beneath where operating enough pollen will fall from a tree well furnished therewith sufficient to impregnate the trees deficient thereof. To go over the trees every other day whilst in blossom is not a very serious affair, and may make all the difference in the crop. Care should be exercised in the application of the brush, for if used roughly and heavily the style of the pistil may be injured or the viscidness of the stigma removed; but done with a light hand and at the right time it is desirable, it is certain to be beneficial, and is a process which I should not feel easy in omitting when the trees are in blossom at the dullest period of the year. In the fertilisation of the blossom notice will be made of some with two pistils, notably Noblesse, Grosse Mignonne, Early York, and the Peaches and Nectarines with large flowers, and these give twin fruit, not one in twenty of which do other than fall after setting, rarely passing stoning. They should be removed, and this may as well be done at blossoming as any other time.

The adventitious or twice-flowering or more of some fruits has been noted, but I do not remember the Peach and Nectarine being included. About four years ago an Early York had several blossoms late in September, and set the fruit well, swelling to about the size of Peas, and again this year a Nectarine we had for Elruge, but it is the Roman, of which Parkinson wrote in 1629, "It has a large or great purplish blossom like unto a Peach," and Dr. Hogg says, "Is one of the oldest if not the oldest Nectarine in cultivation," which had in the middle of November a fruit the size of a pea. This adventitious flowering I have found when prevailing to only a small extent a good augury of future prospects.

I will now allude to the advancement by stages of the fruit of the Peach and Nectarine. The first stage is that immediately following setting. Many fruit after setting swell to the size of peas and become stationary, swelling very little for near a fortnight; some fruits swell rapidly, and with others the footstalk shrivels and the fruit falls. If cut through these fruits are found to be imperfect. I was under the impression that this dropping of the young fruit was due to over-setting—too many fruit for the trees to support; but acting upon it by reducing the fruit after setting convinced me of my error, for some fell just the same, whilst others swelled. Inspection of the flowers prior to impregnation led to its being attributed to the defectiveness of the female organ on the one hand and of the inertness of the pollen on the other, but in most instances the former. I allude to this because it has been advised in cases of a preponderance of flowers to thin them, resolving itself into a question of which may and which flowers may not be removed. It is easy in the case of Apple, Pear, Plum, Cherry, to tell the flowers by their want of ovary and smallness as non-setters, and the large blossoms, with large ovaries and stouter footstalks, as the setters; but in the case of the Peach and Nectarine the large flower showing the ovary very clearly at the base set only to drop when the size of a pea; whilst the medium-sized flower upon weaker wood, with the ovary prominent, sets and retains its hold with a tenacity exceeding that of the larger flowers on strong wood, whilst small flowers with no apparent nectary almost invariably drop with the petals. It is clear that the flowers to be thinned are the weakest, but in what way their removal can contribute to the setting of those retained is, to say the least, questionable and uncertain. The only good I think that a removal of superfluity of blossom can effect is the diversion of matter from

expenditure on useless bloom to improving and invigorating the growing parts, and acting in that way, if it does, must contribute immensely to the after-support of the fruit and vitality of the tree itself.

The next stage to which I will allude is the commencing of the stoning process, and the advantage is here in favour of the moderately vigorous tree and the weak, for the vigorous tree casts its fruit to an alarming extent. If the fruit be cut we find a kernel of watery matter, or the dried empty skin of the seed, or hollow cavity, the footstalk of the fruit dried up, and the fruit itself shrivelling. There is a cause for this no doubt, yet what that may be I could never ascertain. It is clearly not an effect of treatment nor of overcropping, but, contrary-wise, luxuriance of growth. Can it be that the growth being gross the ascending sap is imperfectly elaborated in the fruit, and the descending juice or cambium is diminished in proportion from the great loss consequent on the excessive exhalation from the leaves and fruit surfaces of gross trees as compared with the moderately vigorous? This I think is the case, for, first, the fruit invariably shrinks; and second, if a ligature be placed on the branch or shoot bearing fruit below the fruit so tight as to compress the sap vessels, the fruit seldom drops. I contend, therefore, that as the trees at this stage grow but slowly, that the process is being undergone in respect of the fruit similar to that occurring later on in respect of the wood—viz., its ripening. The ascending sap being excessive, growth and unfruitfulness ensue; but the ascending sap being moderate, the descending is greater correspondingly from the lesser exhalation taking place by the leaves and fruit, and the parts are more fruitful. The casting of the fruit at this stage is analogous to that described in the "Science and Practice of Gardening," page 386, summed up in the following terms:—"A similar defective fertility occurs if the female parent in animals is over-stimulated and fat."

The third stage is the stoning one, and this is certainly, in respect of the fruit, similar to the ripening of the wood. The seed is with the completion of the stone perfect, as with the ripening of the wood the buds are rendered fertile or otherwise abortive. The two last stages are dependant upon the condition of the parent. It is not a result of imperfect impregnation, but of grossness of growth, or its opposite, weakness, and resultant from overcropping. If the growth of the trees be gross, and much wood is made during the stoning, few fruit will pass it safely; and in the case of a weak tree, from the ill supply of nutriment, the fruit, if at all abundant, does not stone, a number of fruit dropping, but not to such an extent as in the gross subject; whilst the moderately vigorous tree, with stout short-jointed wood, not overcropped, and its growth stationary or nearly so during the stoning period, passes the stage with the loss of few, if any, fruit, and what do fall are the small and imperfect.

The importance, then, of the ripening of the wood or the deposition of cambium is essential to the fruit passing the first stage, also the second and third, and points to our avoiding the extreme of moisture and over-stimulating food during those periods or those immediately preceding, "inasmuch as an abundant supply of these increases excessively the development of the succulent parts of the fruit, and yet the vessels from this to the seed often wither and render it abortive."—*Science and Practice of Gardening*, page 386.—G. ABBEY.

## CHAPTERS ON INSECTS FOR GARDENERS.

### No. 4.

THOUGH it is but a word of three letters, I consider the word "fly" to be one of the broadest words in the English language, since it serves in its popular acceptation to cover such a multitude of insects. Besides flies proper we have no end of flies improper rejoicing in this appellation. Many species of the Hymenopterous order are flies with most folk; so are the dragon flies, the May flies, and other Neuroptera. The Hemipterous aphids and sundry relatives rejoice in this epithet, and so do the caddis flies. More than that, the name touches the unlikely order of the beetles, for a *Haltia* is a Turnip fly; and day-flying species amongst the gaudy tribe of the Lepidoptera are butterflies, or even simply flies. In fact it might not be difficult to establish the theory that originally English folks called every insect that could fly a fly; though, on the other hand, there is no evidence that people called insects which did not fly a "creep" or a "crawl," yet it would have been quite as appropriately vague. Flies, however, to speak scientifically, constitute the important order of the Diptera or Two-winged

insects, placed by some writers on entomology at one end of the insect class, and by some writers at the other end. As we work from the lower to the higher the consideration of it comes here. To most persons the name at once suggests annoyance or loss, and visions come up of the house fly, the bluebottle, the gnat, the mosquito, the gadfly, and less-known species of a like evil repute, while the horticulturist has his special reasons for disliking the Diptera; and yet these insects render important services to mankind at large, and some services worth mentioning to the flower, kitchen, and fruit garden. Pre-eminently are the scavengers of the insect race represented amongst the flies; and their labours in decomposing and devouring substances which would otherwise be noxious or at least useless, were recognised long centuries ago by the man who in old Greece and Italy groped eagerly and painfully after the truths of natural science.

So far as numbers are concerned flies take the lead amongst insects, though in point of size many of the species occupy only a low place. Flies have not inappropriately been termed the pioneers of the insect host, for it has been observed that on barren lands which have been brought under cultivation, and where insect life was previously lacking, the first species that present themselves are these two-winged insects. I dare say a look of disgust steals over the face of many a gardener as he contemplates the "insects of the sunshine," about which the poets have gone into rhapsodies, and most of which belong to the Dipterous order, and wishes they would take their aerial excursions anywhere else but in his domains. Yet really I, for my part, would venture on the assertion that on the whole we have more reason to view the Diptera with friendliness than with disfavour, though I know there are some who would maintain the opposite. It is certain that of the multitude of flies one sees about the garden or the conservatory the majority are only intent upon imbibing the honey of flowers and have no sinister designs, and a proportion of them are directly or indirectly beneficial to us. Of course there remains yet a proportion that are injurious either in the fly state, or, more frequently, while in the larval or maggot condition. Meanwhile I would urge the reader to keep in mind these four facts, which I put as curtly as possible lest he should say emphatically in the words of a popular refrain, "Bother the flies!" First, then, various larvae of flies do service as scavengers in preparing decomposing matter for the enrichment of the ground; secondly, many flies as imagoes and larvae prey upon other insects, and also on other flies; thirdly, the fertilisation of flowers is frequently brought about by the passage of flies from one blossom to another; and fourthly, flies supply an important element of food to numerous birds which would otherwise attack vegetation. It is well known that when much damage is done to the buds in spring the birds who have been concerned in the matter have had difficulty in obtaining sufficient insects for their requirements, and so they fall upon the tender leaf buds. Of course I grant that sometimes the birds open buds for the sake of the insects they contain.

The particulars which need to be noted to enable us readily to distinguish the bulk of true flies are brief and simple. The two wings are clear and are never folded, while in place of the hind wings found in other orders we have a pair of balancers or poisers ending in a small knob. The mouth is best known by its proboscis or sucker, rendered still more effective in some species by an accompanying array of lancets, representing what amongst the biters of the insect tribes we call the mandibles and maxilla. The pupa of a fly is always inactive, nor does its shape give any clue to the insect enclosed. The familiar maggot or larva is legless and most usually simple in form, though a few species with aquatic habits are curiously decorated with appendages having to do with the breathing or swimming apparatus like that of the common gnat. The eyes are large, sometimes seeming to absorb the whole of the head. In the structure of the legs we notice that the tarsus (which represents what we call the calf in the human subject) has five joints, the feet being clawed and provided with flat hairy pads, generally two in number, occasionally wanting. These pads enable flies to perform those feats, so astonishing to the eye, in the way of walking head downwards on substances which offer no grip; and even when the structure of the fly is examined there is still some difficulty in comprehending "how it's done." Flies, however, are not the only insects thus skilled in gymnastics, though they have been spoken of as if they were singularly clever in this mode of progression.

The very small division of the flies called the Eproboscidea only require a few words, as they do not concern gardeners,

since the flies in their mature condition are parasites on the bodies of animals, and a few species are without wings. The forest fly is a familiar example of the winged type of the division, and the sheep tick, so called, of the wingless. In this group we have the most peculiar circumstance of the female insect producing but one individual, and that either an adult larva or a pupa. The bulk of the flies form the Proboscidea; again divided into the Nemocera, slim creatures mostly, with longish threadlike antennae and long legs, and the Brachyocera with rather stumpy antennae displaying a fine bristle at the base, though a few have these longer, but not jointed as in the Nemocera. Though the majority of the species in the order belong to the latter group, we notice the former group about us quite as much, from the habit they have in many instances of congregating in parties—gnats and midges for instance. But without venturing on a close calculation, I compute that the gardeners' enemies of the Dipterous race preponderate amongst the Nemocera. It is not always easy, however, to distinguish friend from foe, not only in the case of flies but with various other insects, because a vegetarian in one stage will be predacious afterwards, and vice versa; so that the benefit may be more than a set-off against the injury received. Some entomologists, again, have endeavoured to break up the Nemocera into two natural divisions of Blood-sucking Flies and Flower-lovers, not very successfully as yet.

We may take it, on Mr. Walker's plan, as dividing itself into ten families, the rather obscure family of the Mycetophilidae coming first, although its representatives are small in size but excessively active, seeming to skip almost as frequently as they fly: in popular phrase they would be called tiny gnats, though they have shorter legs. The larvae feed on fungi, also on decaying vegetable matter, or perhaps sometimes on decomposing animal substances, and they can hardly be said to affect horticulture either favourably or unfavourably. I am not aware of any authentic instances where they have done mischief to the edible fungi cultivated in our gardens. Far more important is the next family of the Cecidomyiidae, embracing the myriads of the gall gnats, many species of which must be counted amongst the gardener's foes, though the result of their operations is a disfigurement and not the death of the plant attacked, nor an arrest of its fructification. Few species of Cecidomyia trouble the orchard or the kitchen garden; still there are exceptions: thus in 1874 *C. nigra*, at first suspected to be a different insect, destroyed a good many Pears. It is the habit of the species, as we conclude, to deposit eggs on the Pear bloom, and the young larvae or grubs, eating in, bring the fruit to the ground at an early period immediately after they are knit. No one, as a rule, takes any heed of these small windfalls, especially when a certain proportion remain behind, and so the insects are suffered to increase and multiply. As Mr. Newman observes, such abortive Pears should be carefully picked up and burnt to insure the destruction of a part of the imagos, though no man can secure himself from these winged visitants if they chance to come from his neighbours' orchards. Some years ago a Cecidomyia was very active in disfiguring the leaves of the Ash in gardens and plantations, and there is a well-known species that attacks the Raspberry canes, causing swellings which are seldom attributed to the insect that really is the germ of the mischief. Everywhere, in the garden and the wild, do Cecidomyiidae occur, the malformations they develop in leaves and flowers being sometimes of very singular shape. The woody galls, however, are generally produced by Hymenoptera, though the gall gnats frequent certain of the galls of that sort, not as parasites but as visitants, living amicably with the rightful tenant, as is supposed. It is a question, though, whether intruders into a gall do not under some circumstances starve out the gall-maker. In the case of several flowers the larvae of these flies bring about abnormal growths; thus, in those of the Tansy, when it is attacked, the stamens and style have been observed to disappear, while the corolla was unnaturally shortened. On the Ground Ivy the larvae of a species of Cecidomyia feed in small case-like dwellings which are readily detached from the plant, reminding one of the tent-abodes of the caterpillars of numerous small moths of the Coleophora tribe, in shape resembling a cigar. Small as are these larvae, many of them journey from the plant to the earth, into which they enter to become pupae; and a correspondent of a scientific journal asked curiously, "What is the fate of the Cecidomyia larvae that have completed their term of larval life on the boughs of Willows and Osiers overhanging water, since, if they followed

their usual habit and descended they must tumble in and be drowned?" To which a rather extensive observer of galls has replied that the insects will seldom be found occupying such situations, the parent flies instinctively avoiding these branches. Some of the gall gnats make silken cocoons. Agriculturists have reason to consider the word Cecidomyia a name of terror, since serious damage is committed by *C. tritici*, the Wheat fly. This autumn I noticed the species swarmed in some fields in the North Kent districts, and it is most difficult to deal with.

In dismissing the Cecidomyiidae I gladly give them a favourable note at parting, and therefore state that some of them assist the Coccinellae and the Syrphi in thinning the numbers of the aphides. Apparently they "do good by stealth" if they do not "blush to find it fame." Indeed, one discovers that the aphides have far more insect enemies than was once thought; and it is a fortunate fact, otherwise through their vast fertility we should suffer from them still more severely, since all aphides seem born with good constitutions, and in weather that is most trying to humanity they can be "awfully jolly."—C.

### NORRIS GREEN,

THE SEAT OF J. P. HEYWOOD, ESQ.

MR. HEYWOOD's name is well known as a chief banker of Liverpool. Norris Green is situated at West Derby, about six miles from Liverpool. My visit was not marked with the most propitious weather, for the rain fell thick and fast from early dawn to 1 P.M.; this was in the month of August, and the day of my visit was said to be the wettest day of the season, yet I was determined on seeing Norris Green despite the rain.

At the entrance gates is a substantial lodge of red sandstone, passing which a good broad sweep of well-kept carriage drive brought me to the mansion. On each side the drive is a thriving belt of shrubs. Hollies in particular seem to thrive better in this locality than they are generally met with in the more south and easterly counties.

The mansion is a plain substantial-built residence, pleasantly situated. In a north-easterly direction the eye looks upon a richly wooded landscape stretching some miles away. From this point is obtained a bird's-eye view of Knowsley, the noble mansion of the Earl of Derby, and from the same standpoint a view is obtained of Croxteth Park, the seat of the Earl of Sefton. The western side of the mansion is shut in by tall trees and belts of shrubs, for the purpose of shelter and shutting out the public highway which runs close by.

To the left of the mansion is a good sweep of well-kept lawn, next comes a group of fine old Beeches, &c.; this is called The Rookery. Beyond this a belt of large trees extending far in a gentle sweep to the north-east; this gives a background as well as shelter. A walk extends through this wood.

Retracing our steps we now come to the winter garden and conservatory. It is a sunk or panel garden, and is 100 yards long by 36 wide. Formerly it was the flower garden proper, but owing to the family being away during the summer months the enclosure is now converted into a winter and spring garden. It is planted with choice kinds of flowering shrubs, such as Ghent Azaleas, choice kinds of Rhododendrons, Mediterranean Heaths, Fernettyas, Kalmias, Andromeda floribunda, Daphne cneorum, &c. The shrubs planted by the sides of the walks are Golden Yew, *Taxus aurea*, *Cupressus Lawsoniana* erecta viridis, and *C. fusifera*. A few beds are left for bulbs and summer-flowering plants. By a judicious arrangement of three sets of bulbs these beds are kept gay a considerable time, first set being Crocuses, second Hyacinths, third Tulips. They are all planted at one time, in new soil, early in the autumn, about 2 inches deep. By this system a succession of bloom is obtained, one set closely following the other, leaving no blanks in any part. After flowering the bulbs are taken up and afterwards used for border purposes, fresh bulbs being planted every year. These are followed by ordinary bedding plants. The vases round this garden are filled with low-growing plants, such as Sedums, &c., with Ivy growing round the pedestals.

The conservatory is at the end of the garden. Beyond is a walk 150 yards long by 10 feet wide, planted on each side with Conifers—*Picea Nordmanniana*, *P. nobilis*, and *P. insignis*; *Deodaras*, *Wellingtonias*, *Araucaria imbricata*, and *Arbor-Vitae*. These on each side are sheltered by large forest trees; but Conifers do not seem to thrive well after they attain a certain height, for strong westerly winds are powerful here, and the dense volume of smoke and fog which passes over this locality has its baneful effects on some kinds of shrubs. For such

localities the dwarfier kinds of Conifers are better suited, where they can be sheltered by large-growing trees.

The conservatory is 71 feet long by 40 wide, and is built on the ridge-and-furrow principle, and has four entrances. A walk 4 feet wide runs round the sides, the central walks being 5 feet wide; these are edged with stone and covered with a light-coloured shingly gravel. A stage is round the sides of the house 2½ feet wide for small plants. As will be understood by the arrangement of the walks, this leaves four compartments. In these compartments are planted Camellias, each plant being separated from the others by a single-brick partition wall. No doubt this is a wise provision in the event of any one plant requiring to be removed, so that it would not in any way interfere with the adjoining. Each division contains about a dozen exceedingly fine plants. They are grown as pyramids, in a soil about two-thirds of loam and one

of peat, with a little silver sand; in the spring and summer months they are watered with farmyard liquid manure diluted with rain water. They were bristling with bloom buds, which have been judiciously thinned, so that good blooms may be looked for. The following are the dimensions of a few of the plants:—*Camellia Chandelieri* is 8 feet high by 5 through; *imbricata alba*, 8 feet by 6 feet; *Cheloni*, 8 feet by 5 feet; *elegans*, 10 feet by 5 feet; *Waltoniansis*, 7 feet by 5 feet; *Aitonii*, 7 feet by 5 feet; *francfurtensis*, 6 feet by 4 feet; *Lady Hume's Blush*, 9 feet by 6 feet; *imbricata rubra*, 9 feet by 6 feet; *reticulata*, 8 feet by 4 feet—this is grown as a standard, and is rather a difficult one to grow well; *Saccol Nova*, 10 feet by 8 feet. At the corners of these divisions is a plant of *Azalea indica alba*, 6 feet by 5 feet. The roof of the conservatory is supported by eight iron columns, braced together by girders. On these are trained *Gloire de Dijon* and

Fig. 107.—NORRIS GREEN.

*Maréchal Niel* Roses, *Tasmania Van-Volxem*, *Acacias*, and other choice climbers. These were growing in unconfined profusion, thus having a more natural and pleasing appearance than when trimly trained. This house is efficiently heated by two saddle boilers.

The kitchen garden and forcing department is a walled-in enclosure. The first house we enter is a span-roofed stove 40 feet long by 20 wide, with a stage round the sides and a pit in the centre. In this pit is a hot-water tank, over which is placed the plants. Noticeable was a fine plant of *Dracena lineata* 10 feet high, a good plant of *Allamanda Schottii* finely in bloom, also some very fine plants of *Eucharis amazonica*, choice Orchids and Ferns. Next comes a half-span Cucumber and Melon house 54 feet by 17 feet. The Melons grown were *Royal Ascot*, *Green-fleshed*, and *Cox's Golden Gem*, which are highly spoken of. Next in order is a range 160 feet long by 19 feet wide, divided into four compartments, a central compartment being for plants, which contained a good collection of *Azaleas*, &c., of convenient sizes, which have when in flower to do duty in the conservatory. The other compartments are for early and late-keeping Grapes. *Lady Downe's Seedling* and *Black Alicante* are the best sorts for late keeping, but preference is given to *Lady Downe's Seedling*, which Mr. Child told me keeps in good condition until May. For early Grapes the *Black Hamburgh* is grown. The forcing of

the early house is begun at the end of October, and ripe Grapes are out in April; and as the late kinds are kept until May this gives a succession the year round. One house had been recently planted with *Muscat of Alexandria*, which had covered a rafter 22 feet long, the wood being well ripened and short-jointed.

We next enter a span-roofed house 40 feet by 20 wide, with a pit in the centre and a stage round the sides. The centre pit is filled with soil and planted with choice kinds of Tea Roses, which are trained over iron trelliswork; they are also trained up the rafters. On the side stages were some nice young plants of tree *Mignonette*, growing-on for conservatory decoration, besides many other plants for the same purpose. This house furnishes a good supply of cut blooms during the spring months. In addition to this house a choice selection of about two hundred plants are forced for decorative purposes.

The next house is a lean-to vinery 45 feet by 18 feet, which is planted with a double set of young Vines (*Hamburgs*), the permanent Vines being planted in an outside border while the temporary Vines are planted inside for earlier forcing. This is done with a view to cropping the temporary canes only until the permanent Vines are thoroughly established.

My attention was next directed to a span-roofed house 45 feet by 15 feet, with a walk down the centre and a pit on either side also planted with Vines; this is a late house, the

sorts being Lady Downe's Seedling and Alicante. This was not originally intended for a vinery, but merely for a temporary purpose. Sentence of death had been passed on these Vines, but in consequence of their continuing to bear crops of such excellence the sentence has been withdrawn during Mr. Child's pleasure, a decision I quite agree with.

Next is a lean-to range about 240 feet long by 12 wide and 12 high in four compartments, planted with Peaches and Nectarines. The fruit from the first houses had been gathered some time; in the second houses I noticed good fruit of Belle-garde Peach and Acton Scott Nectarines, the whole having produced average crops of good fruit; a late house contained some fine fruit of Pitmaston Orange Nectarines. At each end of this range is a gable or span entrance; on the front side these entrances are planted with Figs. These with the usual cold pits and frames complete the glass structures.

Large quantities of Chrysanthemums were growing on for decorative purposes. The large-flowering kinds are grown on single stems, which at the time of my visit were from 4 to 5 feet high; the Pompones are trained on low flat trellises. The larger-growing kinds when in bloom are placed between the Camellias, which help to light up the more sombre-looking foliage of the latter. It is no light task to keep this large conservatory gay through the dull months of autumn, winter, and spring. To show the extent of the forcing required for such a purpose, I may mention that five hundred Roman Hyacinths, and about the same quantity of various colours are employed, besides a thousand Tulips, eight hundred Crocuses, one hundred and fifty Narcissuses, two hundred Lilies of the Valley, one hundred and fifty *Spiraea japonica*s, supplemented by Primulas and *Justicia speciosa*, of each about a hundred plants, spring-struck; Cyclamens, Celosias, and Cocks-combs. *Begonia waltonensis* and *parviflora* are found very useful, also large quantities of flowering shrubs, such as Ghent Azaleas, Rhododendrons, Lilacs, and a host of other plants too numerous to mention.

A wide border in front of the principal range of houses is planted with ordinary spring flowers, such as Daisies, Violas, Polyanthus, Myosotis, &c. A short distance from this border is an Italian garden, which is filled with three sets of bulbs the same as previously described. At the back of the principal range are the young men's bothies, potting sheds, &c. It is worthy of remark that their comforts here are studied more than they are in many places. The apartments were clean and healthy, and consist of kitchen or mess-room, which contains a good cooking range and separate bedrooms, the foreman having a room to himself; there is also a woman attendant.

The kitchen garden contains the usual assortment of fruit trees, &c., except Peaches and Nectarines, which are grown under glass. Noticeable on a west wall was a fine crop of Morello Cherries. About twelve hundred Strawberry plants are prepared annually for forcing; Duc de Malakoff, Viscountesse Héricart de Thury, Sir J. Paxton, and President are forced in the order named. The greater part of the vegetables are grown a little distance away, the ground devoted to their culture being about four acres in extent.

Leaving the kitchen garden by a short cut we arrived at two semi-detached cottages with neat gardens and abounding with sweet-smelling flowers; these cottages are occupied by Mr. Child and the coachman. I must not omit to mention that in addition to the comfortable housing of Mr. Child and his young men the labourers are not neglected, for near at hand is a row of comfortable cottages. This is a worthy example on the part of Mr. Heywood, and would be better for both employer and employed if the example was more generally carried out; it would tend to cement master and man more closely together, and the advantages of such a plan cannot be over-estimated. It is too often the case that men have long distances to walk morning and evening, and it must be obvious that a man having three or four miles to walk cannot be so fresh for his daily labour as one who is close to his work. Mr. Child's staff consists of thirteen men—viz., nine labourers and four journeyman gardeners, the whole of which are employed in the houses on wet days.—G. R. ALLIS.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

Winter having set in severely and somewhat suddenly has very much altered the sort of work to be done; for what would have been a busy time for planting and ground work should now be devoted to such work as will forward operations when

the weather proves favourable. On the 8th (Friday) there were 4° of frost after a heavy downfall of snow; but this morning (Saturday) the thermometer registered 18° of frost, but this did not come on till the morning, and by eleven o'clock the glass stood again at the freezing point. Now it is hoped that the previous advice given about the preparation of protecting materials has not been neglected, for they will now be wanted in real earnest. The wet season we have had, which in so many districts has caused a temporary flooding of the soil, has caused many plants in the kitchen garden to be more sappy or tender than a finer autumn would have brought about, consequently that one circumstance will, if the frost last long, cause a greater destruction by it. In many gardens about here the crop of Celery is poor: in order to save as much of it as possible the most of it should be protected by litter or straw, or even branches of evergreens. Again a whole row may be taken up, leaving as much root as possible, and take the plants to a shed or cellar, and lay the roots in dry earth. If the frost should penetrate the earth so as to reach the plant I am afraid that much of it will suddenly rot when a thaw takes place. That is my reason for stating that much of it should be taken up. The heads turning in of Snow's Winter Broccoli have been cut, and as the plants remaining of this and other sorts are covered with a thick coating of snow it will be well to let them alone, as snow, if it comes before frost in sufficient quantity, is a great protector. But where Broccoli suffers considerably is when a sudden thaw comes on so as to melt the snow off the plant and then suddenly freezing again, the plants after that are liable to go off at the most tender part—just under the heads.

Watch carefully the heat in outdoor beds of Seakale and Asparagus. If the heat is at present sufficient it will be best not to do more than add an extra covering of dry material to keep the heat in as much as possible. In former times when these plants were more frequently forced outdoors it was no small trouble for gardeners to keep up the heat; thatched hurdles were often called into use to stand round the beds and keep in a lining of dry straw between these and the heated dung. Whether the plants are in a frame or a dung bed these protectors should always be prepared, for they are excellent aids and applied in a few minutes, and as easily taken away when not wanted. Whoever may be collecting fresh manure for an early Cucumber bed should, if possible, put it under an open shed, or if that is not convenient it should be protected from frost and snow outdoors, both of which hinder the process of fermentation and render the bed dangerous from rank steam when put up. Leaves from trees are useful to add to the manure.

In the fruit garden I am afraid if frost comes on too severely that some of the tender sorts of fruit trees will suffer; for I see the wood of Peach and Nectarine trees is very imperfectly ripened, and of the late sorts many of the leaves are still hanging green upon them. Now a temporary protection of evergreen boughs stuck among them would do no harm, but probably prevent much injury, and these any amateur can obtain and they are quickly applied. Fig trees on walls may be treated in a similar way. In such early winters as this the plan of thatching the trees in upon the wall is not a bad one; it saves the young wood if not the fruit; it would, however, be a long job with large old trees whose branches have been allowed to grow too much out of bounds. Young wood may be gathered up into a comparatively small space and tied together, and protection made easy. Though gardeners in large places have much of this sort of protection to resort to, it is necessary to success and applies with the same importance to the amateur though in a much smaller way.

Now the opportunity is come do not neglect to have plenty of labels made of different sizes both for kitchen-garden crops and indoor plants, also flower-garden pegs made, flower stakes made, and old wall nails cleaned, shreds out, and everything arranged for convenience at a more busy time.

The store of fruit should be looked over, and take care that the temperature does not fall too low; it ought to be kept at about 50° Fahr. The same may be said with Potatoes, which ought not to be below 40°.

In the greenhouse watch that the heat may be also kept very regular and by no means too high—say about 40°, which will keep most plants in a proper state at present. A hot dry heat when the weather is too severe to admit of ventilating the house is one of the most injurious plans of treatment, and should be guarded against in every possible way.—THOMAS RECORR.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

##### HARDY FRUIT GARDEN.

Winter has come upon us rather suddenly this season, and those are fortunate who have their trees planted out and a thick mulching of short manure placed over the roots. Should packages of trees arrive in severe weather, or at a time when the ground is not in a condition for them to be planted, they

must be laid-in carefully, and not be planted when the ground is frozen, or if it is saturated with wet. We look over all trees in the open borders at this time, and prune where it is required. The system of summer-pruning has a tendency to overcrowd the branches, and if this is the case the fruit is not sufficiently exposed to the influence of sun and air; nor will fruit buds be formed in the thickest parts of the trees at all. The pruning knife should be used freely in the way of thinning-out the wood; there is little danger of overdoing it.

Gooseberry pruning will also be done as soon as it is convenient. It may be as well in this also to remark on the nature of the bushes to become crowded with young wood. This must be cut quite close back to the main stems, except so much of it as may be required to extend the tree or to fill up spaces. The points of the shoots only ought to be cut off. Any suckers or young growths from the base of the main stem should be wrenched out without leaving any buds from which growths may start the next season. If the bushes were infested with the caterpillar it will be necessary to remove the soil underneath the bushes to a depth of 3 inches or more, and wheel it on to a space of ground where it may be trenched-in to a considerable depth. Some fresh rich mould from the same ground will be required to replace what has been removed. This pest may also be destroyed by placing some fresh tan under the trees where the eggs of the caterpillar have been deposited. The Gooseberry season is very much prolonged either by planting a few bushes of the latest sorts on a border on the north side of a wall, or the trees may be trained to the wall itself. One of the best sorts for this position is the Red Warrington.

Red and White Currants are pruned much in the same manner as the above. The young wood is spurred back closely to the stems, the leading growths being cut back to three parts or half their length, or even closer, just as the bushes have grown to the full size or otherwise. The leading growths should always be cut to an outside bud, which will cause the leading growth next season to grow outward instead of into the centre. Black Currants require but little pruning—only to have the branches cut out where crowded, or to get the bushes into shape. They have also a tendency to throw out from the base, but none of them ought to have more than one stem. Bushes can be obtained at such a cheap rate that it is hardly worth while for an amateur or gardener to propagate their own, unless it is desirable to perpetuate some favourite variety. The strongest young wood should be chosen for cuttings, and it should be removed from the bush with a heel. To prevent suckers from springing up all the buds must be removed with a sharp knife that are underground when the cutting is planted. They must also be cut out 4 inches above ground, leaving only about from three to five eyes at the top.

We would again urge the importance of annual, or at least biennial renewal of Strawberry beds. We noticed a man the other day digging between the rows of a Strawberry bed. He had first to set a line, and cut down the side of one, and then measure the distance between the next row, as all traces of the original plants were lost in a confusion of runners. Now we have often grown Strawberries in this way, but have never been able to obtain more than half the quantity from the rows that could be obtained from one-year-old plants, and the quality from the young plants has always been of the best.

#### FRUIT AND FORCING HOUSES.

**Vinerias.**—We are preparing some fermenting material for the earliest house. A thick coating sufficient to cause a gentle heat is placed upon the outside border after it has been watered with tepid water, and to retain the heat shutters are laid over the manure. Equal proportions of stable dung and leaves cause the best heat, and retain it longest. When the thickness is not more than a foot or 18 inches, in six weeks the heat will have gone out of the covering, when it may be renewed by removing some of the most decayed portion and shaking the rougher part up with fresh material. If it is necessary to apply water this can be done at the same time. The Vines always start most strongly when there is a bed of the same material inside the house. As soon as the heat becomes excessive the material may be turned over; indeed, this may be done every day with advantage to the Vines. It is not necessary to syringe in the house much when a bed is made up in it. It is necessary to look over the bunches about twice a week to cut out decaying berries. Mrs. Pince's Black Muscat has kept very badly; the berries decay in the centre of the bunches, and it is not easy to remove them without injuring the outside berries. Bunches of Gros Guillaume quite as large and compact as those of Mrs. Pince have not had any berries decay. Lady Downe's Seedling keeps very well, and looks quite as fresh as they did in September.

#### GREENHOUSE AND CONSERVATORY.

Early-flowering Tulips and Hyacinths that have been plunged out of doors should be removed to shelves near the glass; the crowns will have started an inch or more, and the pots will be quite full of roots. A small pot should be placed over the crowns for a few days to gradually inure them to the light. A

few pots may be placed in the forcing house or early vinery; but the heat at night ought not to be too high at the first—45° will be sufficient. If the pots can be plunged in a little bottom heat it will cause a more rapid growth.

Roses may now be started in the same temperature. They ought to be pruned six weeks at least before starting; if they are pruned just before they are apt to bleed. *Deutzia gracilis* is very easily forced, and is one of the most useful of our decorative plants. It is not necessary to go into details of culture, as all these early-forcing flowers require very similar treatment. They are all better to be started gently at first, and, then, with increasing heat, and the plants kept as near the glass as possible, they will flower freely at any time during the winter months. All are the better of a little bottom heat.

Hardwooded plants, such as Cape Heaths, Asaleas, and other New Holland plants, do not require very much attention at this season, but what they do require must be done at the proper time. They must have as much air admitted by the ventilators as possible; but during such weather as we have at present, with a keen frosty air and a thick fog through which the sun's rays cannot pierce at noonday, it has not been possible to open them all. Of course had we houses that could be spared for each class of plants the night temperature for nearly all this class would not be so high, and air would be admitted by day on occasions when it cannot be done at present owing to the house containing more tender-flowering plants. Cape Heaths are very much subject to the attacks of mildew, and when it first seizes hold of the plant it cannot be discerned without minute search, so that those who are not aware of its insidious progress are often taken by surprise. Dusting with flowers of sulphur is a sure remedy, and when applying it the plant should be laid down on its side to prevent the sulphur from falling into the pot, as it is very injurious to the roots.

Asaleas have been trained into their proper shape, and some of them have been placed in heat for early flowering. The plants that still remain in the greenhouse require looking over occasionally to remove decaying leaves. They are free from thrips and red spider. Both these pests hang about the leaves in winter, and where they are now on the plants the house should be fumigated with tobacco smoke, as no better period could be chosen than this to destroy them. The smoke will not kill the eggs; when these are hatched another application will be necessary.

One seldom sees the *Cilanthus punicus* in a healthy condition, and with it may be named *Pimelea spectabilis*. They are both very difficult subjects to deal with, but they need not be so if the plants were watched for the attacks of spider. In nine cases out of every ten this is what causes the leaves to drop off prematurely. Another mistake that is sometimes committed not only with these but other hardwooded plants is this, the mould in the pots is allowed to become too dry. The plants do not suffer so much at this season from that cause as they would when they are making their young wood, but they do suffer, consequently it is better not to allow them to become overdry. It is not possible to describe exactly the state of dryness that the roots ought to be in before they are watered, but it should not be to the extent of the ball parting from the sides of the pot, and when water is applied the whole mass of roots should be saturated.

*Lapageria rosea* and the variety *L. alba* are now in flower. The last-named sort that had pure white flowers in September is now producing them tinged with delicate pink; but what a useful plant this is for producing flowers at a time when fine flowers are scarce! The plant has seldom been without them for more than a quarter of a year. Some persons complain that it is not easily managed, but with the right treatment, either planted out or grown in pots, no plant can do better. It does not succeed in clayey loam, and many persons both plant it out and pot it in that material. It grows most luxuriantly in turfy peat, with the addition of a little sand if necessary to keep the material open. The roots should always be kept in a moist state, as the plant never seems to be at rest. Strong succulent growths are thrown-up either at midsummer or midwinter.

The Filmy Ferns, which are usually grown in a glass frame in a shady part of the greenhouse, require a little attention at this season, as the fronds sometimes decay and spread contagion to those that are healthy. *Todea superba* and *T. Fraseri*, with the *Hymenophyllums* for a groundwork, are well adapted for this system of culture. They are not only remarkably beautiful, but all this class of plants are instructive to the intelligent cultivator. We pot all of them in a compost of three parts turfy peat to one of turfy loam. The case must be kept a little moist in winter, and in fine days the inmates may be gently dowed overhead. Very little water is required at the roots at present.

—J. DOUGLAS.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

HELENSBURGH (Recess). July 18th and 19th, 1876. Mr. J. Mitchell, Sec.

## TRADE CATALOGUES RECEIVED.

The Lawson Seed & Nursery Company, 1, George IV. Bridge, Edinburgh, and 54, Bishopsgate Street Within, London.—*Catalogue of Forest Trees, Shrubs, &c.*

William Chater, The Nursery, Saffron Walden.—*Catalogue of Hollyhocks and Roses.*

Thomas Sampson, Yeovil, Somerset.—*Catalogue of Gladioli.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Fruit and Forest Trees and Evergreen Shrubs.*

Kelway & Son, The Royal Nurseries, Langport, Somerset.—*Catalogue of Gladioli.*

Francis & Arthur Dickson and Sons, The "Upton" Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees, &c.*

Deafosse, Thulliers & fils, at Orleans.—*Price Current of Fruit Trees, Roses, and Ornamental Plants.*

Charles Verdier, fils, 23, Rue Baudricourt, Paris.—*Catalogues of Roses, Fruit Trees, Gladioli, Herbaceous Plants, &c.*

Robertson & Galloway, The Nurseries, Helensburgh.—*Catalogue of Liliums and Gladioli.*

## TO CORRESPONDENTS.

\*. All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**COLOURED PLATES OF FRUITS (E. Richardson).**—The finest work is Deane's "Jardin Fruitiier du Muséum," but it is very expensive. Van Houtte's "Pomona" is much more reasonable in price, and contains very excellent portraits of the leading kinds of Pears.

**MOVING AUCUBAS AND EUONYMUS (—).**—As soon as the snow is gone and the ground is sufficiently dry to enable you to work it properly, Aucubas and Euonymus may be moved with safety.

**INTRODUCING CAMELLIA TO HEAT FOR FLOWERING (A Subscriber).**—You may place the plant in a day temperature of 60° and night 50° for to expand the flowers if you require the plant to flower at an earlier period than it would do in a lower temperature; but if the buds were set early it would flower readily at this season in the lower temperature named. Camellias and Oranges might be kept in a house in which Cucumbers are started in March until they have completed their growth, and should then be removed to a cooler and drier house, the former having shade from bright sun.

**EUPHORIA SPLENDENS LOSING ITS LEAVES (Idem).**—The removal of the plant from a warm house, and undergoing a journey of some distance, is sufficient to account for the leaves falling; they, however, generally fall at this period if, as should be, the plant is kept dry up to February, after which water being given it will flower in April, and continue to do so for several weeks.

**OXALIS CULTURE (H. G. M.).**—Of the easiest culture, we are surprised you cannot induce them to flower, and growing luxuriantly. It appears you give them too liberal treatment, and keep in the shade at some distance from the glass in a shaded and moist position. Grow them on shelves near the glass, potting when they are beginning to grow in a mixture of three parts light fibrous loam, one part leaf soil, and two parts sandy peat, with a part of silver sand, watering moderately until in free growth, increasing the supply with the growth, and after flowering, or the growth is complete, diminish the supply, ceasing watering when the leaves become yellow, and keeping dry until the plants again start into growth. They do well in a light airy position in a greenhouse. Their great bane is too much water and shade.

**HEATING POWER OF DUPLEX STOVE (Idem).**—You mistake as to the heating power, or alleged heating power, of "the portable greenhouse stove." It is not presumed that it will keep frost out of a house 20 feet square, containing as it does 400 square feet, and your house will have 198 square feet, the heating power of the stove being such as to exclude frost from a house of at least a quarter the size of yours, such as many amateurs have, and derive great pleasure from it only they can safely winter the plants they have reared in summer, which the aid offered by these inventions enables them to accomplish. To exclude frost from your house would require two 2-inch hot-water pipes all around, equal to a heated surface of 58 feet (superficial) at a temperature of 200° to be safe in severe weather, and for that you will require a stove boiler with 2-inch hot-water pipes.

**DIVIDING AGAPANTHUS (J. N.).**—The best time to do this is in May or when commencing growth, the flowering being past, and this you may do by removing the soil, and disentangling the roots, part into as many divisions as you wish plants, taking care to have a crown to each division with its roots. A compost of three parts fibrous loam, and a half part each leaf soil, sandy peat, and well-rotted manure. Good drainage and very free watering during growth is necessary, with sprinklings overhead frequently until the plants are established, and a rather closer and moister atmosphere with slight shade from bright sun, afterwards expose fully.

**PROTECTING HARDY FERNS (A. F.).**—The Ferns being hardy will not require any protection except in a bleak position, and then some sort of shelter to break the force of cutting wind is all that would be required branches of evergreens answering well.

**MANURING GROUND FOR POTATOES (Idem).**—It is quite right to manure the Potato ground at this time of year, throwing up the ground roughly for the winter, especially as the soil is clay; and the first open weather in or after February, in dry weather only, turn the ground with a fork, throwing level, and apply when the work is complete a dressing of quicklime at the rate of a bushel per rod (80 square yards), and before planting point-in with a fork. The ground, unless it has been cropped with Potatoes every year without change, would grow Potatoes without invariably failing from disease. Plant kinds that mature by July or early August, and you will have a minimum of disease.

**ORCHID TREATMENT (M. J. T.).**—*Cypripedium splendens* is a variety of *C. caudatum*, and is synonymous with *C. caudatum superbum*, and requires

the soil and treatment of the other kinds requiring stove treatment. We have seen it in fine flower in September and March. *Olanthe vestita* oculata flowers at this season, and requires to be kept rather dry, having a dry stove, for if moist the flowers spot. In spring it commences growth, and should be repotted, using lumpy brown peat, with a fourth very fibrous light loam, a fifth of old dry cow dung, and a sixth each of lumpy charcoal and silver sand. Plenty of moisture when growing, and dry when at rest. *Bolbophyllum speciosum* is probably *Oncologyne speciosa*, which flowers in late summer, for which cultural hints are given in the "Orchid Manual."

**CLIMBER FOR STOVE (Idem).**—*Pasiflora kermesina* has bright red or crimson flowers, and would succeed in a temperature of 50° to 65°. Williams's "Select Stove and Greenhouse Flowering Plants" and "Ornamental-foliage, Plants" may suit you.

**SELECT CHRYSANTHEMUMS (L.).**—Large-flowered: Empress of India, Golden Beverley, Lord Derby, Mrs. G. Bunde, Laurinda, and Venus. Pom-pone: James Forsyth, Rose Trevenna, Model of Perfection, Saint Michael Aurora Boreale, and Mrs. Hunt.

**COMPOST FOR ROSES IN POTS (Idem).**—The compost for these on the Briar and Manetti stock requires to be rather stronger than for those on their own roots, but being Teas the soil should be rather lighter than for Hybrid Perpetuals on those stocks, as the scion exerts considerable influence on the stock. Three parts turfy medium-textured loam, and one part each old manure and leaf soil, will grow them perfectly.

**PEACHES FROM WALL UNSATISFIED (A Subscriber).**—The best thing to do would be to root out the tree, removing at the same time six barrowloads of the soil that is near the base of the tree, then add the same quantity of turfy loam, or any fresh soil if this cannot be obtained. Plant a Royal George in the place of the tree that you remove.

**TREATMENT OF ESPALIERS (Holly Bank).**—Five feet is a good height to make them, the wires to be 8 inches apart. The borders may be of any width, as the roots will soon extend many feet.

**PRUNING FRUIT TREES (St. Vincent).**—If they were not summer-pruned they must be pruned now, as the young wood, if left on, would branch out next summer and spoil the appearance of the trees. We have always recommended summer pruning, especially if the trees have a tendency to make much young wood.

**SELECTION OF VINES (E. S.).**—Madresfield Court Muscat and Muscat Hamburgh are both well adapted for a cool vinery. Venn's Muscat has not been sufficiently proved yet, except in the hands of the raiser. It is said to ripen at the same time and with the same treatment as Black Hamburgh.

**PEACHES IN POTS (J. T. S.).**—1. They may be grown in pots for man years with annual surface-dressing or repotting. 2. Early Beatrix, Early York, Royal George, Bellegarde, and Barrington; these are the best Peaches for you. Neectarines—Lord Napier, Murray, Pine Apple, Elruge, Violote Hative, and Victoria. Place them in a temperature of 50° early in January. If you do not want late sorts omit the two last named of each.

**VINES FOR COOL VINERY (H. T. H.).**—Duke of Buccleuch, Foster's White Seedling, Buckland Sweetwater, and White Frontignan (as you wish for Muscat flavor) would be suitable white kinds; and Black may be Madresfield Court, Venn's Black Muscat, Black Prince, and Tretham Black. They would all succeed with a little fire heat when coming into flower and when ripening. The distance is rather close. We should advise you only having seven instead of eight Vines. Two rows of 4-inch piping along the front would be sufficient for a house of not more than 12 feet in width; but for a house of 15 feet three rows of 4-inch pipes would be required, it being better to have too many rather than too few pipes, as the heat is best given off at a low than high temperature.

**RANUNCULUSES (Sussex).**—They like a deep rather moist soil, well and deeply dug, well manured now, and the ground thoroughly exposed to the weather. The Persians are the most beautiful, having finely-formed flowers. The Scotch have fine spotted flowers; and the Turbans have Peony-formed flowers, larger and earlier than the Persians. Have a bed of each; or if you can have but one, take the Persians in the named varieties.

**POINSETTIA TREATMENT AFTER FLOWERING (Poinsettia).**—Keep dry, not allowing the wood to shrivel, and out down in March, putting in what outtings are required, selecting the firm ripe wood, and strike in brisk bottom heat. The temperature after flowering should be 60° from fire heat, and 6° higher by day from the same means. Water moderately after the plants are started into growth, sprinkling overhead twice daily, which will be sufficient moisture to cause them to start into growth, and repot when the plants have shoots an inch long. A moist atmosphere, with careful watering at the roots, taking care not to over-water nor to allow the plants to flag, keeping near the glass, and well ventilated, so as to induce a sturdy growth, and a temperature 55° to 60° from fire heat, and 10° to 15° or 20° rise from sun, keeping power and drier after early August.

**PIPING FOR CONSERVATORY (Elin Lodge).**—Your piping must be single, or you would have were it double—i.e., a flow and return pipe, 60 feet of 4-inch, and 40 feet of 8-inch piping, sufficient to give you a temperature from fire heat of 50° to 55°; but we should have them all 4-inch, and a flow and return along the ends, the half of one side, and the whole of the other, as shown, and this would give you 100 feet of 4-inch pipes, enabling you to have the temperature required without heating the pipes to a high temperature.

**INSECTS DESTROYING OXYLAMENS (—).**—The grubs which have out through the roots of your Oxylamens are the larvae of the destructive weevil *Oxyrhynchus sulcatus*. The earth ought to be carefully sifted and the grubs destroyed. The beetles which are produced from these grubs are nocturnal, and must be sought for after dark with a light.—W.

**NAMES OF FRUIT (T. E. Cobb).**—The fruit is Duchesse d'Angoulême, in a state in which it is often met with in unfavourable seasons like the past. You have not numbered the other sorts. The large one is Doyenné du Comice, the second largest Napoleon, and the small one we are not certain about. (E. T.).—The brown-russeted Pear is Burré Bosc, and the green one is Léon Leclerc de Laval; the latter is a stewing Pear. (Penge).—3. Bad Goubault; 4. Cruesande; 5. Knight's Monarch; 6. Colmar; 7. Huyake's Victoria. (J. O. W.).—Apples: 1. Blenheim Pippin; 2. Golden Noble. Pears: 1. Red Doyenné; 2. Comte de Lamy; 3. Achau. (Alberti Withington).—1, not known; 2 and 8, Comte de Lamy; 4, not known; 5 and 6, Golden Winter Pearmain; 7, Herefordshire Pearmain; 8, Dunselow's Seedling.

**NAMES OF PLANTS (W. Reed).**—1, Pinus exelsa (?); tree should be seen to be certain; 2, Cryptomeria japonica; 3, Picea pinsapo (Lobbi is its synonym); 4, P. cephalonica; 5, Cedrus Libani (perhaps Decadars); 6, Cupressus macro-

carpa (or *Governans*—tree should be seen); 7, *Pinus cembra*; 8, *Juniperus chinensis mascula*; 9, *Abies Smithiana* (*Morinda* its synonym); and 11 cannot be determined unless from good specimens from the tops of the trees.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS DE L'ANGLETERRE.

#### CHAPTER VI.—PENSURST.

We climbed up one of those beautiful hills so peculiar to Kent, where the wild flowers nestling among the dark green shade of the ferns lined the banks. It was called Smart's Hill, and smart truly it was in the clothing of August flowers. When we reached the top we looked down upon the valley beneath and on the distant hills beyond, and took our fill of one of those panoramas of beauty that this part of Kent is so rich in. It was worth while coming to see the view alone. There was Penshurst Place lying below among the fine trees, and on the hills beyond near a score of village churches could be counted among the distant woods; while here at the top, close to where we were standing, was Mr. Boissier's poultry establishment.

This yard has only been started about four years, but the owner's name is gradually working its way into the various prize lists. Rome was not built in a day; and those fanciers, if they are worthy of the name, who buy the best birds of the season and show them to death, or let them fall all to pieces, are as meteors in the paths of the poultry world. Weariness, despair, disgust fall upon them and their reigns are short, for their names disappear as quickly as they came. Not so, however, with Mr. Boissier: he has bought good birds from good yards, and, satisfied with reasonable returns, is now beginning to reap the reward. It is just as much pleasure to us to visit the rising establishments as those of veteran fanciers, and so in our peregrinations after les basses-cours we like to look up everybody.

The establishment we are writing about is one of those where small moveable houses with small changeable runs are chiefly used. Mr. Boissier has given up a fair-sized field to his birds, and all over the place we find these runs dotted about. Each little house will hold four or five birds. They are built upon a plan of their owner's, and in many ways resemble those of the Messrs. Crook's; but Mr. Boissier has exercised his own ingenuity and turned out really capital little houses for the kind. Each house is on wheels or can be moved with handles, and each has a small moveable wire run attached to it. These little places are moved in a circle, and being moved every two or three days the birds are always on fresh grass. By this means the whole of the field is gradually worked over, while between each movement the grass has time to get fresh and to grow again. The chickens are loose in the field, and many of the hens when not breeding; but the cocks cannot be allowed to have their liberty, as the pens are only made of ordinary wire netting, and they would consequently fight with each other. Old bags or coarse canvas can be laid over these little wire runs in the sunny time of day, so that the birds can always have plenty of shade. We really were quite taken with the methodical way this department was worked and with the general healthy appearance of all the birds.

There were other fixed houses in blocks, which, though quite roughly made and built at no great outlay, still the birds looked well in them; and our ideas were once more strengthened that birds well fed and attended to do better in cheaply made serviceable houses than ever they do in those wonderful erections that we sometimes see with coloured glass windows and elaborately constructed roofs. We must not forget to mention a capital arrangement for sitting hens. It was like a long row of rabbit hutches, all moveable, with a strong well-eaved roof. In each compartment was a floor of grass, and there the birds could incubate without any fear of disturbance, while, standing as they did in the open air, the nests are always fresh and without offensive odours. There was also a small block of houses and runs, built in the shade, for single cocks, which we should say would answer the purpose well, though, had we been the architect, we should have made them rather larger. The part, however, which struck us the most were the moveable houses and runs, and the systematic way in which they seemed to be arranged. We had often heard of these pens being so used, but never saw such a group of them before in such thorough working order.

Now we must turn to the inmates of the pens. We find them many and various. Crêves, Houdans, White Cochins, Black Hamburgs, Light Brahmas, and Booted Bantams we saw, many of them really splendid specimens and mostly in wonderfully robust health and condition. Mr. Boissier in forming his yards looked out for fanciers who were retiring from some especial breed, and then bought all their stock. In many cases this was successful, for we find his chickens a very creditable lot. Still we do not advocate this plan, for the new purchaser, having no knowledge of the peculiarities of some of the birds, must mate them with a certain amount of risk. If going in for a new variety ourselves of which we had no particular knowledge or

experience, we should prefer leaving the selection of a good pen for breeding purposes to some honest and straightforward breeder. Among Mr. Boissier's birds we were much taken with the French. The Crêves especially were a very fine lot of birds, being remarkable for crests and good combs. We believe they were principally of Mr. Feast's strains, and the success of this gentleman's Crêve cock for three years in succession at the Palace, though now no longer in his own possession, speaks well for the strain. One or two hens we admired immensely, but all were good in colour. The Houdans we found in a moulting state, many of them, but their frames and shape betokened their quality, and Mr. Boissier has been successful this season with their chickens both in his own name and others. The Black Hamburgs were a fair lot, but the chickens' combs lacked the north-country shape. We do not wonder exhibition Hamburgs are few and far between in the south, for their combs are awkward things to breed good naturally. These three breeds were in a large block of fixed pens on one side of the poultry field, with trees shading them in the rear. In the single-cock pens we found some nice White Cochins and a good Crêve cock or two, but these were also in process of changing their plumage. In another block of fixed houses and runs were the Light Brahmas. The hens were especially good; the one which took the cup last January at Portsmouth was moulting nicely. The produce of these birds, too, were certainly above the average, and many have realised good prices, for Mr. Boissier is always ready to take a fair price for his birds. One cockerel we then thought highly of we saw a few weeks afterwards well to the front at Edenbridge, from whence he speedily went to a new home, we hear.

In the moveable pens, all over the field, were the White Cochins and White Bantams, and they really looked very striking. We saw two good old cocks which, we are sorry to learn, have since met untimely deaths, but the hens were the best, and very nice birds many were. Some of the chickens, too, were very promising and have since come to the front as we expected they would. All the intervening space between the runs, and all over a shrubbery and small farmyard, were the younger chickens, which will be in their turn penned in the moveable runs when they come to the years of discretion. We must not forget to mention the Booted Bantams. There was a very nice little stud of them, and we have watched Mr. Boissier's successes with them with much pleasure.

We spent so much time over the little pens and their inmates that the afternoon had almost waned before we left the chickens' field, but we were obliged to have a peep at the Rabbits, for they looked so clean and healthy in their admirably constructed hutches. There were Himalayans and Silver-Greys, the former really extremely good in all points, and their owner told us he had been very fortunate with them. After this a hasty peep round a very pretty garden arranged with the utmost taste, where the colours in the beds, too, blended most beautifully, and then we passed once more on to the high road and descended Smart's Hill. As we went down we thought over the yards we had left, and came to the conclusion that Mr. Boissier had too many irons in his poultry fire. It is all very well for those who keep a manager, or those who go into the fancy for the sake of the profits, to keep a great number of breeds; but for a gentleman who simply keeps them for a hobby and gives personal supervision to them we are quite convinced two, or at the most three, breeds are sufficient. We are glad, then, to see Mr. Boissier has himself realised this; for from the weekly King Street advertisement we learn that Mr. Stevens had authority to sell without reserve, on the 7th inst. last, all the Crêves, Light Brahmas, and Black Hamburgs from the Penshurst yards. Valuable though the specimens mostly were, still we do not think Mr. Boissier will regret this step, and we wish him much success with his reserved forces, for he will now be able to bring them to much greater perfection, and to spend more time in producing chickens worthy of the breeding stock he has at Penshurst.—W.

### BRISTOL POULTRY SHOW.

THE tenth great Bristol Exhibition of poultry and Pigeons will be held on the last day of this year and the first and third days in next. On the first page of the little book we find the subscription list, and the total amount comes to about £80. This is not a large sum, and considering Mr. Cambridge so nobly caters for his poultry friends single-handed, we feel sure all will do their best to support him and prevent his venture being a losing one. The entry fees are as usual, and the last day of entry is December 7th. Admission to the Show will not be allowed to anyone until the awards are made, and in making this rule we know Mr. Cambridge means to keep to it. Double baskets will be allowed, and will, we are sure, bring many extra entries. The prize birds will be offered by auction on the first day of the Show at 2 p.m. An especial rule tells us that no telegrams relating to prizes won will be answered on the day of judging. The Judges are announced—viz., for poultry Messrs. Hewitt, Teebay, and Dixon, and for Pigeons Messrs. P. H. Jones and

Charlton. There are twenty-two silver cups to be awarded in the poultry classes; of them one, value £10 10s., will be given to the best pen in the Show, in addition to any other cup. The rest of the cups are chiefly £5 in value. The classes are well grouped. There are four divisions for nearly every variety, two being for adults and two for chickens. We are glad to see Black Cochins have classes. Brown Leghorns, Malays, Minorcas, and Polish have two classes each. We think the latter variety could have been more subdivided to the advantage of the funds. Bantams are well cared for, but it always seems to us so curious that the Variety Bantams have no class even here. We cannot conceive why they should be so shut out, for if one of the other classes was merged into a variety class—say that for clean-legged Whites, we are convinced it would be more satisfactory to all. Waterfowl are well provided for with many classes and substantial prizes.

The Pigeons are well looked after, having thirty-four classes, eight cups, and two point cups. We find Carriers have six classes, Pouters four, and Barb three. The other Pigeon classes are much as usual. We imagine the point cups will bring out many good teams of birds and make the large exhibitors enter well, having friendly rivalry one with another to see who shall win these silver trophies. We know many object to these point cups, but we never could see how they injured the small amateurs; for the latter class never enter the specimens of their own specialities with these cups in view, and so the disappointment is not for them, and they have all the same as much chance of winning with their entries whether point cups are in use or not; for even if birds are borrowed for the occasion—not that we advocate the system of borrowing—it cannot hurt the amateur whether they appear in the names of Mr. A or Mr. B. Let all come to the front and try to make the Show of this winter as good a one as we found in the Drill Hall on the last occasion.

P.S.—Through the length of our Birmingham report and other pressing matters last week we regret that the above had to be omitted; but we feel sure Mr. Cambridge will still accept the entries of those exhibitors who had been waiting for our usual notice of the schedule if they will now enter by return of post.—W.

#### WHITE-SKINNED SILKIES.

These are fine fowls, and will no doubt become popular. They are quite different in some respects from their black-skinned relatives, and much superior on the table, in appearance at least. At three months old they make very delicious broilers of a nice size. Their appearance is odd; crested, bearded, and with feathered legs, red combs, and wattles, we think them handsomer than the purple-visaged birds, besides having the advantage of more size. They have some traits which should make them rivals to Bantams. They lay well, hatch splendidly, are excellent mothers, while as chicks they are very hardy, mature quickly, and forage well. A four-foot picket fence will restrain them within bounds, while they will thrive and look happy in less space than any breed yet known, Bantams being almost wild compared to them.

We believe there are as yet but one or two flocks of this variety of fowls in this country, and none in England. Those here are mostly, we think, the descendants of two cocks and four hens, imported from Japan in 1874 by Mr. George H. Carey of New York. Three of the original birds are still living and vigorous. There is no doubt that the white skins of this importation make them a valuable addition to our poultry.—(*American Pet Stock Bulletin*.)

#### THE YORKSHIRE SOCIETY'S EXHIBITION OF POULTRY, &c.

This was held in the Cattle Market, York, November 30th and December 1st and 2nd. The Judges were for Poultry Mr. R. Tebbay, Fulwood, Preston; Pigeons, Mr. H. Brown, Walkley Sheffield; Rabbits, Mr. M. Millington, Colliergate, and Mr. A. Hudson, Paragon Street, Hull. The following were their awards of the prizes:—

even a highly commended. *Hamburgs* were admirable: all the classes were well represented and the quality good. Mr. Long sent a good team of birds, but many of them were adults, and they wanted more time to show off well. It seems to have been a very slow and bad moulting season. Perhaps the *Asiaties* have come out the best, but we have seen but few birds that would not even now have been better for three or four weeks longer. Silver-pencilled *Hamburgs* was the weakest class, but the winners were well up to the average. The second-prize Silver-spangled hen was poor in markings, her mate must have pulled her through. In Blacks the hens and pullets were better than the cocks. The latter seemed to lack colour rather, and be a shade coarse. *Malays* made a small class, as they have done generally this season. Mr. Hinton walked off three prizes with three good lots of birds. The noticed pens were also good. In the Minorca, Leghorn, or Andalusian class splendid specimens of the former variety won all three prizes. The winners were very good, the first-prize hen a beauty all round. *Bantams* were many in numbers, and the quality was good, especially in the Variety class, where capital Blacks were first, and Gold and Silver-laced second and third. In the Any other Variety class Silver Polande of good quality were first, and second and third neat Black Poles, the hen in this pen being especially nice in crest. The highly commended birds were good, and comprised Silkie, Sultans, Geese, Turkeys, &c. The Sale classes were very fair, the two first-prize pens of Dorkings certainly the best. *Waterfowl* very nice; the first Aylesburies good, ditto Rouens, and the winning Black Ducks certainly very lustrous and small; second to fancy, and third to same exhibitor's other pens. Highly commended good Call and Wild Ducks.

**Pigeons.**—The classes were very large and the quality generally good. Mr. Hammock brought down an immensely good team of birds, and committed great depredation among the prizes. His Blue Carriers were grand, perfect in wattles and fine in shape. Tumblers also and Pouters were good, and Mr. Hammock once more was an easy victor, though the third White of the latter breed closely pressed on him. Dragons had two classes, and the quality was capital; Mr. Gregory's Blue was a nice bird, and cheap at catalogue price of 40s. Owls very good in every way, and many pens came in for the Judge's cards. Turbits quite beautiful. Mr. Salter won again with his young Black, a good bird in every way; second to the same gentleman's neat Silver, which had a very good head. Jacobins good; Red, Yellow, and a Red won in the order named, the first being admirable in colour. Fantails made a very interesting class; the winners were all Whites, and their places good. Magpies were again a nice collection, and one exhibitor cleared off all the three prizes with three good exhibits. Antwaps were a large lot—half a hundred or more; the class was even in quality, and winning precariously. The Variety class was very varied and very pretty; a grand Black Trumpeter won of the Russian type, good in every way. The Sale class was very nice, and we saw one or two cheap pens of birds. We furnish full awards below.

DOMMONS, -1 and Capt. T. C. Burnell, Micheldale, 2, E. Barnett, North  
Falkenstein, 3, Mrs. H. Vivian, Ac, A. Whaley.

**BIRMINGHAM POULTRY SHOW.**

(Continued from page 487.)

Polands, *White-crested Blacks*.—It is a pity that this beautiful variety is not more popular. We do not think them delicate where nice cover is provided in wet weather, and certainly none look more beautiful in an exhibition pen. Only six cocks and three pairs of hens were entered. The first cock was a beauty, with an immense, well-formed, and very white crest. The second had a round crest, but not such long feathers in it as his predecessor. We liked the highly commended bird much, but he had an inclination to a parting in his tuft. Hens.—The first-prize pen contained one very good but old bird, which shows many traces of gray about her, and has a horribly deformed foot. In the second-prize pen, again, one bird was superior to the other; but taken all round the second-prize pens were very good.

**Golden cocks.**—Here we should have put the second-prize bird first. His crest was not quite so large as the first, but it was much freer from white, and he was in splendid condition, with a fine flowing dark tail. The crest of the first was his point, but what tail he had was nearly white. Hens.—Both winning pens were good, with little to choose between them. We liked the highly commended pair; one of them was most beautifully laced, but they did not quite match in style.

*Silver cocks* were a fine class, every pen being noticed. First had a fine tuft and small spangling; second marked between lacing and spangling. Mr. Adkins' highly commended pen (1804) had a breast spangled like a *Hamburg* in beautiful fashion. Hens, too, were a splendid class; the three pens which failed to gain prizes being all very highly commended. The cup pair, magnificent birds, had the marking between lacing and spangling. One of Mr. Adkins' very highly commended pens (1808) had been we saw claimed for £20, on account probably of their markings being much more inclined to the true form of spangling, which we believe was once common.

Mr. Dixon judged the Polish.

**ANY OTHER VARIETY.**—This class brought together a very interesting collection. We cannot say that we thought the awards all well bestowed. First were *Andalusians*, the hen with hardly any comb—a great deficiency in our opinion. Second very beautiful *Jungle Fowls*, well placed; the hen much resembled a *Silver Pheasant* hen. We were informed by Mr. Leno, their owner, that they were hybrids between the *Bankiva* and *Sonnerata* *Jungle Fowl*. Their price being £5 they were soon claimed. Third were "*Black Indian Game*," in reality *Malays*, and as such they ought to have been disqualified in this class. Fourth *Sooty Greys*; the cock had feathers on his feet, the greatest blemish in this breed. Nothing is easier than to breed lumpy *Cuckoo* fowls with feathers on their legs, but the breeders of the true *Highland "Check Merlin"* will not look at a bird so adorned. There were many good birds in the class, *Silkie*s, *Sultans*, and *White Hamburgs*. Her Majesty the Queen received a commendation for a pair of *Rose-combed Dominiques*.

Mr. Bailly judged the class.

**GAME.**—*Black Red* cocks were an excellent class. Mr. Matthew's cup-winner was a bird of extraordinary style; he seemed to us to combine the fine colour of the old-fashioned type of bird with the long form of the modern. Second a very good bird, but without the style of the cup-winner. Fourth a large and remarkable bird. *Cockerels*.—The winners in this class were good, but beyond them there was much rubbish. We suppose the season has been a bad one for *Game* chickens, for we were quite surprised at the representatives of some yards. The first cockerel was a grand bird; had his hackle only been a little more grown he would, we think, have had the extra prize which went to the *Brown Red* cockerel. His owner refused £30 for him in the Show. In hens we thought the style of the second-prize bird better than that of the first, otherwise they were well placed. *Pullets*.—This was a large class. The cup went to a beautiful bird, but we should have been inclined to place the second-prize bird, belonging to the same owner, first, and his fourth-prize pullet second.

*Brown Red* cocks were an excellent class and well judged, the same bird winning first as at the Palace. *Cockerels* were as a whole a better class than the *Blacks*.

*Reds*.—First and second were very equal. The first-prize bird, which we believe was second at the Palace, received the cup and Messrs. Billing's extra prize for the best *Game* cock in the Show. The fifth-prize bird was, we understand, the *Crystal Palace* cup bird. He did not look in cup condition at Birmingham. Hens were not as a rule a good class, many of them not having good black eyes. The winners were very fair. *Pullets* were an extraordinary good class and well judged. It must have been no easy task to make so good a selection from such birds.

*Duckwings*.—Cooks were a fair lot and well judged; the Palace winner was left out. *Cockerels* numbered eighteen. We much preferred the first and third birds to the others. There were three or four other good-looking cockerels in the class. A class for *Silver Duckwing* cocks brought but five entries. We much admire birds of this hue and would gladly see more of them. Hens were a super-excellent class far beyond the other *Duckwing* classes. The winners were all A1, and the highly commended birds worthy of prizes. *Pullets*.—Some good birds were to be found in this class, but they were strangely placed, the first winner being in our opinion one of the worst in the class.

*Black and Brassy-winged* cocks were a fair lot; both prizes went to *Brassy-winged* birds. Hens.—The first-prize pullet, a *Black*, looked as if she had brown-red blood.

*White and Pile*.—In the class for cocks there were many good birds, but the Judge seemed to have a strong preference for yellow-legged birds and left out many excellent willow-legged ones. The cup went to a rich-coloured *Pile*. Second was also a *Pile*. A nice *White* bird (*Saunders*) was highly commended. Hens.—The same exclusion of good willow-legged birds took place in this class. The cup went to a beautiful *Pile*, which was claimed for £20. Second another good *Pile*.

The *Undubbed* class for cockerels was a good one. Why the class should be confined to birds of the year we cannot see. Most of them go home to be dubbed as soon as the season of such classes is concluded, and their ostensible object is defeated. First prize went to a *Black Red*, second and third to *Brown Reds*.

Mr. Smith judged the *Red Game*, Mr. Lowe the *Duckwings* and *Piles*, and Mr. Lane the *Undubbed* class.

**BANTAMS, Gold or Silver-laced.**—This variety we are glad to see is partially recovering in numbers from the monopoly of one or two great breeders. Nine pens were shown. First of course was Mr. Leno, with beautifully-laced *Silvers*, to which the cup for best pen of Bantams other than *Game* was awarded. Second were *Golden*, a good pen. Mr. Hodson's *Silvers* were well-marked, but too yellow in ground; and several otherwise good pairs of *Golden* were too large.

*Whites* mustered nine pens, more than of late. First were a fair pair, the cock's comb larger than we like. We preferred the style of the second-prize pair.

*Black* were badly judged. First a poor falcon-tailed cockerel and a large hen; second contained a bad cockerel. The best pen in the class was Mr. Cambridge's unnoticed one; 1885, highly commended (*Draycott*), was also good.

*Any other variety.*—First a curious and pretty pen of *Black-booted*, a trifle large; second were speckled birds, *Indian* we presume.

*Black-breasted Reds* do not hold their own or fill the enormous classes they did a few years ago. First were a stylish pair, the cock with hardly enough colour on wing. Second prettily formed, the hen with an even dark breast, a little big. Third a pen in which the hen had too many light shafts in her wing-feathering. We much admired the shape of the cock in the fourth pen, but he is too big.

*Brown Reds*.—The cup went to this variety—a very good pair; the cock small and specially taking. The second-prize pair we thought too large.

*Duckwings or Piles*.—The first prize in this class went to a pretty pair of *Piles*; second and third to *Duckwings*.

There were two classes for single *Game Bantam* cocks; in that for *Reds* the cup went to a singularly good *Black and Red*. In the other class a *Duckwing*, good in colour but too heavy in tail, was first. A selling class for Bantams followed. *Game Bantams* won, but purchasers seemed chiefly attracted by two pens of Mr. Leno's *Sebrights*.

**DUCKS.**—The *Aylesburys* this year beat the *Rouens* in weight as much as the *Rouens* surpass them in numbers. The first-prize pair in the Show reached the almost incredible weight of 21 lbs. 9 ozs., while the first *Rouens* only weighed 20 lbs. 6 ozs. We wish that the test of weight might be abandoned in the case of *Ducks* as it has been long since in that of *Dorkings*. The first-prize *Rouens* were certainly very symmetrical for birds so fatted.

*Black East Indians* were a wonderful class, the cup pair magnificent. The second pen, too, contained a lovely drake.

*Mandarins and Carolinas* both had classes, as also had *Call Ducks*, but strange to say but two exhibitors showed them. We suppose they are troublesome to catch.

**IN ORNAMENTAL WATERFOWL** Mr. R. Gladstone was first with elegant little bare-headed *Geese*. Second were *Ducks* whose names we do not know, prettily marked birds, their bills having yellow patches on them, and their foreheads red.

*Geese* were chiefly remarkable, as usual, in the scales. The first *White* pair weighed 58 lbs. 9 ozs.; the second, 52 lbs. 4 ozs. The first *Grey* pair, 51 lbs. 9 ozs.; the second only 39 lbs. 6 ozs.

*TURKEYS* were grand, and many birds exchanged hands at high prices. The weight of the first old cock (88 lbs. 12 ozs.) has been exceeded, but the first-prize hens, weighing 50 lbs., were the largest we have ever seen, and were bought at the auction for 16½ guineas. The first young cock weighed 29 lbs., and young pair of hens 32 lbs. 8 ozs. The *Cambridge* breed, with a dash of *American* blood, seem now to prevail to the exclusion of the handsome *Black Norfolk*.

It struck us that there were not so many sales as in former years, and that second-rate birds were going cheap, while really first-class birds realised high prices. Mr. Percival's *Dark Brahma* pullets were claimed for £30, Mrs. Arkwright's third-prize *Coloured Dorking* hens for £20, Mr. Adkins' very highly commended *Silver Polish* hens for £30, Mr. B. Walker's *Pile Game* hen for £20, Mr. Daff's *Turkey* hens for 16½ guineas, and many other birds realised high prices.

## THE JACOBIN.

THE readers of "our Journal" are presented this week with a fac simile of the engraving of the *Jacabin* taken from the large-paper edition of the "Treatise on Domestic Pigeons," published by C. Barry, A.D. 1765. There are twelve portraits of Pigeons in this book, but the *Jacabin* is by far the best; some of the others are bad indeed. Although no *Harrison Weir* or Mr. Ludlow had then arisen—both artists and fanciers, yet the *Jacabin* being so much better than the other eleven pictures inclines one to think that he who drew it understood the *Jacabin* better than he did other Pigeons.

Here then we have the best picture in existence of the *Jacabin* as the bird was just 110 years ago. Although being an

engraving there is no colour, yet we see there is the bald head and the white flights and tail; moreover, the thighs are evidently dark, the head is small and round, the beak short and down-faced in a slight degree. The bird seems to have the rose, and to be bordering upon a mane; I say bordering, for the division at the back seems to be partial.

I am no slavish follower of exactly what went before us, but desire at any rate that advances should be on the old lines, because the fancy is an historic thing. Those who are sticklers for exactly what was in existence many years ago are naturally old fanciers, and it is usual that old men think what existed in their youth was the best; in old age the past is idealised. Then there is the opposite fault of the young fancier, who has a tendency to disparage whatever is new. But truth as usual lies in the middle path. That there have been changes in the fancy is very apparent, thus: the Turbit was first plain-headed, then shell-crowned, and lastly, as now, point-headed, each taken in

no bad thing, as it adds interest to a show; but toleration there should be, and kindness there must be.—WILTSHIRE RACROX.

I see by "WILTSHIRE RACROX's" report of the Crystal Palace Show that I must rank myself among the "very prejudiced," not a nice class to be in, and on reading it I felt strongly inclined to classify him in return, but what followed more than reconciled me to it, as he presently admits that English Owls "have beauties distinct from the foreign birds; so that as there is only one standard for Owls, he admits all that Mr. Hnie and myself have been contending for. He has therefore only to find another name for his pets, and the matter is settled.

When on Jacobins he gives me what no doubt is meant for a pleasant poke in the ribs when he says, "But tell it not in Dundee, they were all low-cut and clean-thighed." Now as no one but myself, so far as I know, has written from Dundee on

Fig. 108.—THE JACOBIN.

turn an improvement. The English Trumpeter has as a prize bird disappeared; perhaps a mistake. The English Owl, happily, has not, and at the late Crystal Palace Show the best then in Owl points was superior to any African. There must be much latitude allowed in the fancy. Thus it seems in Scotland Dragoons do not take, whereas in England they are a most popular class. Individually I should prefer seeing a good stud of Dragoons, such as Mr. Betsey's, to the best Carriers in the world; but I would not therefore condemn Carriers because they have never been my fancy.

Fanciers who rejoice in the English Trumpeters being killed and wish to destroy the English Owl must learn to be tolerant of other people, and not imagine that they can turn ninety-nine out of every hundred fanciers, the ninety-nine fully believing that the modern prize Jacobin is superior to any other former bird of that name in its additional and very marked points, the mane and the rose. If a minority wish to revive an old type let them offer prizes and try the experiment, as I have proposed. In some matters deviation is allowed even by Judges, as at the Crystal Palace Show the Jacobins in the first-and-cup of four pairs of Pigeons were clean-thighed and low-cut, and far the best they were in true Jacobin points. I like improvement, for where a fancy ceases to advance it must go back; a revival is also

the Jacobin, I am at a loss to know what he means. I never entered upon the colour or marking of the so-called Jacks, it was the form of the bird we were discussing, which is far more important. This is the second time "WILTSHIRE RACROX" has slipped out and talks of low cuts and clean thighs, points never raised by Mr. Weir, Mr. Hnie, nor myself. Is this from a desire to shirk the question? I have an opinion of my own on marking which I will deliver at the proper time. I think, however, as in Owls, "WILTSHIRE RACROX" have shown signs of surrender, for he admits that the hoods of the present Jacobins (so called), "do not come far enough forward," and he is quite right, and it is pleasant to find him admitting so much, and I hope it is an earnest that ere long his better taste will prevail, and that he will soon be found pulling the right way and help to raise such a storm about the hoods of the poor Jacks as will make them pull them up and wear them as they need to do before their fall. Just fancy for a little that a good fancier of the old school could be present at a meeting of Jack fanciers of the present day. How bewildered he would look when he found them talking of manes and roses, and on being enlightened how surprised and shocked he would be. "Can it be possible," he would say, "that the fancy is so fallen since my departure that blemishes are now turned into beauties, and in this age of

progress? Why, we sent such birds (for they would come in spite of us now and then), to the bird shops for anything they would bring to have them out of sight. If this is all you have to show it is a pity you disquieted me to bring me up."—Geo. Ux, Dundee.

### MAUCHLINE SHOW.

THE second annual Show was held at Mauchline in the Temperance Hall and National Schools (the entries being much larger than was expected, the former place was not sufficient for all) on Friday and Saturday last. Although but the second show, the Committee seemed to be thoroughly up to their work, and with an energetic Secretary in Mr. Wallace, the whole was well carried out; but on account of the small size of the Hall the pens were placed three tiers high, the promenades being narrow. The lowest tier was in rather a dark position, the Spanish especially showing to disadvantage, but in these classes were some grand birds, notably the cocks, which were almost uniformly good.

*Scotch Grey* cocks were very good, the first one of the best we ever saw, the other winners losing only in size. Hens were a very even lot; the first, however, was the most perfectly marked we have ever seen. In *Dorking* cocks the first was a massive Dark-Grey, the second a very good Silver-Grey cockerel, but, with the exception of feet, by far the best was the third Silver-Grey cock, which for size, colour, and shape was an extraordinary bird. In hens a Silver was first, Dark second, and Silver pullet third—a very close run. If we except the winners the *Games* were poor, *Duckwings* taking first honours in each case. The medals in the above two sections went to the Spanish and *Dorking* cocks. *Hamburgs* were a grand lot of eight classes with ninety-seven entries, the medal being won by a most perfect Silver-pencil pullet, very handsome, however, with the first-prize Silver-spangle hen. Gold-spangles in both classes were very good, the hens most particularly, but with the exception of the winners in Gold-pencils there was nothing striking. Silver-spangle cocks were good as regards the winners, the first a thoroughly spangled bird. The first in Silver-pencil cocks was far ahead of all the rest. *Brahma Pootras* in both classes were pretty good; the *Cochins*, however, much better, and the medal awarded to a capital Buff cock. Game *Bantam* cocks were not a good lot, but the first was a moderate Pile; second a Black Red, but that he was a little sickly and marked on the hackle would have been first. In hens the first was a smart Black Red, second and third Piles. In the Variety *Bantam* cocks first was a very small Black, second Black, and third Gold Sebright; and in hens the first was a Silver Sebright, most perfect in all points, and the rest Blacks. A Malay was placed first in the Variety class, Crève second, and Gold Polish third; and in hens the first-and-medal was a Gold Polish hen, second Crève, third White-crested Black. *Aylesburys*, both *Ducks* and *drakes*, were large and fine in quality, the medal going to a splendid fallow of this variety, the Rouen Duck running the above very close, far the Rouen Drakes, though good in colour, were not equal to the rest. *Geese* were a fair lot; the first White Embden, second Toulouse, and third Chinese. The Selling classes were well filled with very cheap birds. Many mistakes occurred through the very unwise system of starting each class with No. 1.

*Pigeons*, as before stated, were in the school-room. Pouters, first on the list, were pretty good, but many not in the best show. In cocks first was a good Blue, large, full of style, but a little short of marking on wing; second a grand White, but a little soiled; and third Red, good in all respects but colour, which was a little dull. Hens were—first Black, faultless if we except a suspicion of trimming on one thigh. In Carrier cocks first was a capital Dun well made up, fine in style, neck, &c.; second Black; and third Dun, rather flat-wattled. In hens a grand Blue was first, Black and Dun of fair quality winning the rest. The medal for Pouters and Carriers went to the Carrier cock. In Tumbler cocks the first was an Almond, second Agate, and third Kite; and in hens, first Black Mottles, second Red, and third Agate—a fair lot. *Fantails* in both classes were very good, especially in size and carriage. The *Jacobins* in both cases about the best classes in the Show, and the medal awarded to a very small Red hen, one of the neatest we have seen of late. In Nuns of both classes the winners were very good; in cocks were two very good Reds. Classes were provided for common Pigeons, some of which were common indeed. In the Variety class cocks the first was an Archangel, very brilliant in colour and in fine order; second a Spangled Ice, and third a Red Turbit; and in hens the first was a neat White Owl, second a Black Barb, and third Archangel. In the Selling classes there were not many birds of great value.

*Rabbits* (which are evidently not understood here) had two classes, but out of nineteen entries only the first-prize Himalayan was of any value, all the rest being common.

The *Canary* section was entirely for the Scotch fancy varieties, although there was a class for Mules, in which a Variegated Jonque was first, and a four-pointed Mealy out of the same nest second.

The prize lists were well got up in such a manner as to be of great service to both the press and visitors.

JUDGES.—*Poultry and Pigeons*: Mr. E. Hutton, Pudsey. *Cage Birds*: Mr. Wm. Kerr, Ayr.

### PIGEONS AT THE GALSTON SHOW.

*Pouter*, Black or Blue.—This was the finest class of all in the Show, the pens ran the full length of the Hall. Many of the birds were grand, and must have struck every visitor on entering. First-prize a splendid Black, fine clean limb, but deficient in markings on the crop; second, a Blue, fine limb and style, rather gay; third, a grand Blue, perfection in marking, but rather deficient in limb. Highly commended also a very fine Blue. This class was worthy of a city show. Pouters, any other colour, a smaller class, but contained some fine birds. First a Yellow cock of fine proportions and great size, deficient in marking and crop, splendid limb, but evidently very old; second, a splendid Mealy, beautifully marked, not quite up in limb; third, a fine Mealy hen, rather gay on wing. Highly commended a fine bird, but a bad shade of red. *Carrier* cock or hen.—In looking over the catalogue we were surprised to find that this fine class was all shown by local fanciers. The first-prize, a Black cock, had a peculiar fineness about him not only in style but all over. This class with one or two exceptions was a very good one. *Fantails*, a large class, for quality seldom surpassed anywhere. It contained both White and Black-saddled birds. First-prize looked like a hen, but it was perfection in every point, and also carried the special prize in this and the former class. The saddle-backed birds were very fine, one of them rather large; but a finer collection of the true "broad-tailed Shaker" we have not seen for many years. *Jacobins*, a fair class. First prize awarded to a pair of Blacks. We were not sure they were a pair, but one of them bore all the hues of the original bird, the fine tilted hood and long chain; second, Reds, a pair of fine birds with a little of what is called the "new type." This was a large and troublesome class to judge. *Turbits*, a large and fine class. There was the absence of the shell crown except in one or two birds. All colours were represented, and very fine birds shown. The first-prize pen was very good, showing all the properties, and with a little more age will be ill to beat. Many of the birds in this class were rather young to take good places. Nuns, a very good and large class, all Black excepting one pair (Reds). There was a total absence of "fancy tailoring" here, and yet the foul feathers were very few. Common *Tumblers* consisted of two classes: the first, marked birds, comprising Beards, Balbs, Mottles, &c.; the second, Self-coloured birds. All the colours were well represented, among them a pair of very beautiful Blues, barred on wing. Common *Pigeons*.—This was a strong class, and suited the rising generation and aspiring fanciers well. The first prize was awarded to a fine pair of pure Whites. Variety class consisted of many fine and pretty birds. First prize awarded to a pair (the only pair) of Short-faced Agate Tumblers; they were gems, and fitted to take honours in a city show. Selling class were most appropriately placed on the stage—a great variety of character, form, and show, from the aristocratic Pouter downwards. The Pouters were the best.

Since writing this report we are informed this Show has been an entire success. The Committee has our best wishes.

### BELGIAN CANARIES.—No. 5.

In my first chapter respecting this particular breed of birds (see Journal of June 17th, p. 491) I remarked that "Belgian Canaries are not every fancier's fancy." I still think so, for the trouble and expense attending the obtaining of real good birds are so great that many fanciers direct their attention otherwise, towards cage-birds which may be bred and reared somewhat more freely than Belgian birds. In many cases which have come under my notice I know the outlay has not been the greatest obstacle to surmount, for as much as five, six, or seven pounds, and upwards, have been expended for single birds to breed with and to exhibit. An enthusiast who will spend some eighty or a hundred pounds for the purpose of riding high his hobby-horse in the Belgian fancy (or any other fancy) may be considered to be touched somewhat with "Belgian or Canary on the brain." After such an outlay as this and where disappointments in breeding and numerous deaths have taken place, it is no wonder that some with a good purse at command, who have imagined that they were going to take Canary matters by storm, have retired sickened and disappointed, crying, "*Peccavi*." We have done wrong by laying out so much money foolishly that we intend going out of the fancy." Such instances as these are to be deplored. Before entering into the Belgian fancy it is better to gain a knowledge of the ins and outs of breeding and managing birds of an easier-going kind.

So far as the present exhibiting season has advanced, more birds of the Belgian varieties have been shown at some of the exhibitions than I at one time anticipated. Take for instance

Bath Show, where no less than a score clear and ticked Belgians were entered. At Darlington too there were 17; Norwich (second show), 23; Middlesborough, 7; Hanley, 8; Newcastle, 7; besides those exhibited at Pocklington, Northampton, Oldham, Derby, and elsewhere, amongst the numbers being many really first-class birds staged. From this I am inclined to believe that one of our choicest breeds of the Canary is looking up somewhat, notwithstanding that a few hitherto exhibitors of Belgians have during the past year or so directed their attention more towards the breeding of other kinds of birds.

As a Belgian Canary proper is considered to be a bird of "position," my wish is that it may maintain that "stand" both as regards form and quality of breed, and that the breeders (not forgetting our Belgian cousins across the water who would not wisely by reducing their prices for birds somewhat) may increase twofold—aye, tenfold if possible, for no variety of Canary shown presents so aristocratic an appearance as the often so-termed "ugly" Belgian bird.

I will here give the points of perfection for which Belgian birds are judged. As I remarked in a previous chapter, I believe there are two classes for Clear specimens (yellow and buff). When breeding with Belgian birds it not unfrequently happens that some of the offspring are slightly ticked or marked with a dark feather or so. Such are none the worse so far as true Belgian form or breeding with are concerned, but they are precluded from being exhibited with Clear birds, unless a schedule specifies for Clear and Ticked Belgians. However, the following are the points of excellence of

#### CLEAR BELGIANS.

Beak, slender and clear. Head, small and flat. Neck, long and slender. Back, long and good circle. Shoulders, high and well filled between. Wings, long, compact, and thin, lying close to the body, but not crossing each other at the tips. Chest prominent, but tapering towards the vent. Body, long and slender. Tail long and thin, with the feathers well wrapped over each other, and inclining in circle with the back. Legs, for length and erectness of stand. Feathers, closeness and richness of colour, and not coarse. Feet slender, with nails not twisted awry.

If in compiling or framing a schedule for a show it should be deemed essential to have separate classes for the Clear, and also classes for ticked or uneven-marked Belgians, then such latter birds will be judged by the same points (excepting the tick or mark) as Clear birds.

#### EVEN OR BEST MARKED BELGIANS.

A good specimen should approach in general form—"position"—as near to a Clear bird as possible, but this rarely happens. In addition to good Belgian properties they should be marked thus—Beak, slender and dark. Eye-marks (spectacle-eyed), a narrow mark around each eye tapering towards each side of the head, but neither coming to the front of the beak or on to the neck behind. If a bird should only be marked on the cap or crown and not about the eyes, and the crown mark be of a perfect oval shape, without the dark feathers reaching to the eyes, such mark to be considered of an uniform kind, and looked upon with some degree of favour by a judge. Wings, the outermost flight-feathers to be white, the inner flight-feathers dark, with the same number of dark feathers in each wing, or as near even as possible. Tail, if not clear but regularly marked with one or two dark feathers on each side, to be considered good. The under part of the bird from beak to vent to be as clear and free from dark feathers as possible. The upper surface from the marking of the crown of the head or the eye-marks to be entirely clear to the tail, the wings excepted. The legs to be dark—the darker the better—in each variety.—  
Geo. J. BARNES.

### HARVESTING HONEY—SECTIONAL SUPERS.

No. 2.

In American apiculture an average of 100 lbs. per hive is not uncommon, and an occasional return of 300 lbs. to 500 lbs. not reckoned a miracle. This statement made by one or two men I should naturally set down as Yankee "tall talk," but when confirmed by dozens of contributors to the American magazines who could have no motive to deceive each other, I feel bound to say I stand convinced.

Now comes the question, How they do it? This is how they do it: Where the greatest weight of honey is desired no supering is attempted, but dependance solely placed on the work of the extractor, which was figured last week; and so great is the value of good straight combs estimated that such are readily marketable at about 1s. 6d. per square foot. Large hives (even sometimes big enough to contain twenty or thirty combs) and strong colonies are essential, so that when the honey appears in the flowers an army of bees rally out to gather it in. As fast as the combs are begun to be sealed over they are at once emptied by the extractor and returned to the hive; the process is repeated about every three days, and the constant re-appearance of the wet combs keeps the bees in such a ferment

of excitement that the honey comes in far more plentifully than it otherwise would—more than doubling the yield. On the other hand this extracted honey does not realise more than half the price of honey in the comb. It is equally as pure, but contains more water, not having been evaporated sufficiently before extracting. This excess of water causes the honey to candy quicker than super or run honey. Although enormous quantities are raised it finds a ready market for home consumption, and brings the raisers about the same price as it is sold wholesale in England.

Fig. 100.—Mr. Harrison's super.

Now with regard to what the Americans call "box honey"—we call it "super"—there they furnish us a lesson. I have been grieved to see at our shows beautiful supers of 40 lbs. or 50 lbs. weight, priced perhaps 1s. 8d. or 1s. 6d. per lb. wholly unsaleable for two reasons—not that the price was too high, but that firstly for private persons there was too much and the difficulty of carriage too great, and secondly the wholesale dealers would not buy because there was no way of dividing the combs without cutting and bruising, to the loss of symmetry and weight.

Fig. 110.—Section of Mr. Harrison's super.

Our friends over the water have long ago seen and remedied this by the use of sectional supers. One is now before me as used by Mr. Harrison of California, who has two thousand stocks, and sends to market sixty or seventy tons of honey annually. Such a man should know what is most useful, and I will endeavour to describe his super as well as that of Mr. Isham, who gained the prize for the best super for sending honey to market in saleable form. I may here say I sent over to America etc.

Fig. 111.—Mr. Isham's super.

precisely for these supers in order to exhibit them at our late show, but they unfortunately arrived one day too late—rather

annoying, as their bare carriage cost me 18s. Fig. 109, Mr. Harrison's, is made of pine quarter inch thick, and each section (fig. 110), 1½ deep and 6½ inches high. The simplest instructions to make such a super would be to say, Make a box without a bottom of quarter-inch pine 6½ inches high, 6½ wide, and of any length you please, and cut this with a saw into sections 1½ths deep. Connect the open end of each section by nailing in a stick five-eighths square, one angle downwards. Now, having arranged the sections close together paste a strip of stiff paper along each side, which will hold all together, as shown at a, fig. 109. The ends may be wood or glass as desired. Each section should be furnished with a wax guide straight down the middle of the top bar, and if properly managed the bees will fill each section with 2 lbs. to 3 lbs. of beautiful comb readily saleable. The grocer only has to run his knife through the paper strip, and the comb separates without mess or waste. These sections could be made in quantities under 1d. each, and when filled would readily find wholesale buyers at 1s. 6d. per lb. Mr. Isham's supers (fig. 111) are much more good-looking and also more costly. The top and bottom are of wood 6½ by 2½, the four sides glass held together externally by tin angles which penetrate through top and bottom and are there clinched; internally a pin through the wood at each corner keeps the glass in place. Nicely filled with comb they must be quite tempting, and would no doubt readily draw an additional 6d. for their cost.

Many people feel disappointment at not being able to sell their honeycomb. I have pointed out some of the reasons why, and another is the too high price placed on it: 2s. and 2s. 6d. per lb. is all very well if you sell to private customers, but to such the sale is limited, and where much honey is raised wholesale buyers must be looked to as the great supporters; these of course must make a profit. Two shillings, or at the most 2s. 6d. per lb., is the maximum price retail for honey in comb in the fashionable quarters of London, and at this price the tradesman cannot afford to give more than 15d. or 16d. For run honey there is no market at the price usually asked. Foreign countries send so much of very fair quality, that until a better system of bee-culture is pursued England is shut out of the market. Narbonne honey, good-looking and fragrant, can be bought wholesale at 7d. or 8d., and while this is the case English at 1s. is not readily saleable. For honey in the comb there is no lack of buyers if produced in a saleable form at a saleable price.

I have read a good deal of American bee literature, and I have come to the conclusion that in their summers they have many advantages of us, but their winters are sometimes very fatal to bees, quite counterbalancing the summer's advantages. I do not find that generally the secretion of honey is much in excess of what we have here, but it is not wasted so much. There are, of course, exceptional localities, such as some districts of California, which are favoured by the goddess Flora, but on the whole I think England could hold its own.—JOHN HUNTER, *Eaton Rise, Ealing.*

### HONEY SEASON NEAR LINCOLN.

I HAVE been looking around at several bee-keepers, cottagers, &c., who keep bees, and I find by examining their hives that only one swarm of this season has sufficient honey stored up to keep it through the winter, and it was a swarm that took possession of a hive where the bees had died last winter. It is full of clean combs. I have seen a great many altogether; not one of them had filled a hive with comb, and all are weak in bees. Old stocks are better than swarms. I think they have a little left of what they gathered from the fruit trees in spring. From what I have heard and read this is the worst of all years of late. I fed my swarm in the summer, and in September it was 80 lbs. weight, now it is 38 lbs.

I have joined several casts to swarms, and in only one did I spread the bees on a sheet to catch the queen. I brought her home and kept her seven days in a super with half-a-dozen of my bees, and fed them with sugar. I saw them feed the queen. On the eighth morning she died.

If "B. & W." and Mr. Lowe are right, I think bee-keepers might turn the bees out from old stocks twenty days after swarming instead of twenty-one days, as recommended by Mr. Pettigrew; even a day would be a gain to the turn-outs. If all is well I shall have some to do next season and I will try one, but I have never doubted Mr. Pettigrew's word.

The swarm and a half that I joined together on the 9th of September have done well. I added another to them in the last week of September. On October 21st hive and bees weighed 25 lbs., I ceased feeding; and on November 1st and 2nd the bees brought out some young white bees, so I replaced the feeding-bottle in the top of the hive and I have not seen any since; they are a very strong lot.

Another hive I have been unfortunate with. The brood comb that I put in with a piece of string fell on to the floor-board, and most of the new comb with it. It was so heavy with honey that I expect it has covered some of the bees up. I have not been able to feed the bees from the bottom since. I have fed them

with a bottle from the top. They have built comb from the top again: it is empty. It is very light and weak in bees, not more than 9 lbs. I do not expect to keep them. Will Mr. Pettigrew say if it will be wise to keep a bottlefull of syrup on all the winter? I should not like to lose them.

The two hives have had 2½ stones of sugar at 8d. per pound. On November 20th I covered all up for the winter with hay-bands and bags, and put the hives in a bee house.

I find late-fed swarms fly about very much with the least bit of sun out or a warm day, so I keep them in with perforated zinc.—J. M.

### OUR LETTER BOX.

**PULLETS MOULTING IN DECEMBER (E. B. T.).**—The only circumstances under which we can understand a pullet having the appearance of being moulting now would be from the fact of her being early hatched and having laid, set, and reared her brood. Such cases frequently occur in Sussex among Dorkings; but we think the Brahma pullet would not suffer so much in appearance and plumage. Change of locale would throw pullets off laying for a few days; but a clean-moulted Brahma hen is sometimes difficult to detect among pullets. The head and comb in a hen have a more wrinkled, and so to speak, scaly appearance than those of a pullet. The plumage (new) has more development of quill, and is softer and more fluffy than that of a pullet.

**TEAL MOULTING PARTIALLY (E. B. N.).**—The most probable cause for the unsatisfactory moult of your male Teal is that he was a bird that had been caged some time, and consequently weak after moulting. Such a bird would only resume his perfect plumage by slow degrees.

**CORN FOR FOWLS (J. H. D.).**—All corn for them is better crushed.

### REMARKS.

- 1st.—Fine morning but very cold, and very slight showers of sleet at times all the latter part of the day.
- 2nd.—Snow 2 inches deep had fallen before 9 A.M., and as it continued to fall more or less heavily there was an additional depth by 9 P.M. of 2½ inches, making a total of 4½ inches.
- 3rd.—Fine morning, but snowy at intervals all day; another three-quarters had fallen during the night.
- 4th.—Snowing fast all the morning; extraordinarily dark for a short time between 2 and 3 P.M.; 3 inches more of snow was measured at 9 P.M., when it was still freezing.
- 5th.—Bright and sunny nearly all day, but the snow still lying and the air frosty out of the sun.
- 6th.—Another and still heavier fall of snow during the night, 8 inches being measured at 9 A.M.; snow fell at intervals all day; the wind was rather high, but frosty.
- 7th.—The snow still frozen; and though the day kept pretty fair, snow fell. The principal feature during the past week has been snow, which in the aggregate has been nearly a foot deep, and still lies to a depth of about 4 inches.—G. J. SYMONS.

### COVENT GARDEN MARKET.—DECEMBER 7.

THE heavy fall of snow has checked both business and supply, and, as frequently happens just before Christmas, trade is at a standstill.

From observations taken near London during forty-three years, the average day temperature of the week is (45.0°) and the night temperature (38.0°).

## COVERING AND PROTECTION.

**AMONGST** the most important of the gardener's duties is the protection of the crops and plants which are under his care. He must protect from extreme heat in summer and extreme cold in winter; at the one season he must repel the heat, at the other invite and conserve it. The latter needs only now to be noticed. Many crops which are ordinarily considered to be hardy need some protective care during the inclement season of winter—not, perhaps, that such crops would be otherwise killed, but yet if left to the full exposure of the weather would be deprived of a great measure of their usefulness. Too often the very hardihood of a plant or crop is the chief element which leads to its destruction, or at any rate prevents it being substantially useful. Ordinarily the winter may not be sufficiently severe to kill outright such common crops as Parsley, Cabbages, Celery, Lettuces, Spinach, and autumn-sown annuals; they are considered as "hardy" crops, and are left to "take their chance." They may not be killed, but yet if unprotected may receive such injury as to render them practically useless, and the cost of their production may be wasted for the want of the little protection which might be given, but which is commonly omitted.

The crops named are very common crops, but they are very useful; they are, indeed, indispensable, for if destroyed or become so injured as to be virtually useless they cannot be replaced. I speak after a quarter of a century's experience when I say that by neglect of protective care at this period of the year of these simple "hardy" crops, that the greatest inconveniences are incurred in many gardens during the spring months. Take the matter of Parsley; it is a common crop, it is true, and not much valued when it can be cut by the barrowful, but to trudge in February five miles for a handful, as I and many others have done, teaches us to appreciate the value of even this common herb, and urges on us the necessity of affording it some protection before it is yet too late. If a portion is in square beds, as it ought to be, it is easily protected by placing over it spare lights; and if there are no lights, it is not difficult to make a few straw hurdles, which are invaluable sheltering aids which can be profitably turned to account in many gardens. If it is in single rows, as it commonly is, there is no reason why it should be lost when by the simple process of placing a board on its edge affixed by stakes driven into the ground, the board to slant over the row from the north or east side, it can be so serviceably protected. Even stakes laced with evergreens or straight straw, or, what is better, hexagon netting bowed over and similarly laced, may make all the difference between plenty and poverty of the supply of an article which often causes more unpleasantness than do crops which are usually assessed at greater value. I say therefore, while there is yet time—protect the Parsley.

Have any—but I know they have—had their August

No. 180.—Vol. XXIX., NEW SERIES.

and September-sown Lettuces killed, and when in the bright days of April and May salads have been called for and longed for—even stormed for—there have been none to give? Then how ardently the gardener wishes he had protected, instead of which, with all the nursing and sheltering, even potting, he cannot have the spring-sown Lettuce in perfection until July. Protect, I urge, with hurdles of straw or evergreens, if nothing else better is at hand, and by a little extra work and discomfort now there will be the reward of comfort in the spring, and credit and pleasantness. I say once again—Protect the Lettuce.

**Cabbages.** If this crop is killed what have we in its stead? We have nothing that will fill its place. The Winter Greens are gone and the Cauliflowers have not come in (even if the plants were not killed), and Asparagus and Peas can never stand in the stead of Cabbages. "But we cannot insure the preservation of this crop," some may suggest. Perhaps not always, but do we do all we can? Do we plant in deep drills, as we ought to do, so that the soil is easily placed up to the hearts? Cabbages so planted are seldom killed, and if they are not so planted and advantage is taken when the ground is open to throw up a miniature bank at the cold side of each row, the plants will invariably escape destruction. I know what a northern climate is, and have been tanned with the winds off the North Sea, but I did not lose my Cabbages last winter when the thermometer was down to zero. I say therefore, Protect the Cabbages, for this is a vital crop without a substitute.

**Spinach.** This is another "ticklish" crop ever in demand, and is always worth some protective care. It is injured by wet as well as frost, and is especially tender in light rich soils. It should be grown in an exposed place on dry and not rich soil for the winter supply, and if sheltered with thatched hurdles it is generally there when it is wanted. I have had the pleasure of sending occasional dishes twenty miles as the greatest favour that I could bestow on a friend; and I know a gardener at the present time who would be glad to pay carriage for a parcel twice a week for the next ten weeks to go twice that distance. If at one time this vegetable is regarded as a weed, at another time it is very precious; and even if tolerably plentiful now, it may be unpleasantly scarce two months hence if not protected.

**Cauliflowers** I need not say much about. They are more tender than the crops previously named, and consequently have protection given them—some more than they need—and become first "drawn" and then "buttoned;" they need protection, or the crop may be lost. The same may be said of hardy annuals; with a little preparation and a very small amount of protection they are seldom or never destroyed, but if this little is not afforded them they rarely pass the winter safely. Celery also needs some protection, and we should hear less of the complaints in spring of "My Celery wo'n't keep." It "wo'n't keep" in spring if it is frozen in winter; but litter, or stubble, or evergreens will mostly make it safe. It is not commonly that these useful crops are killed by

No. 180.—Vol. LIV., OLD SERIES.

the first frost of winter—by that frost they are injured—but it is the long cold term succeeding which completes the ruin if shelter is not afforded to encourage their spring growth. Protection also serves another important purpose by sheltering from the sun and insuring a gradual thawing of the frozen plants or crops, a matter which is of the utmost consequence, and should never be disregarded.

It is surprising how effectual is even a little protection. There are few who have not noticed that when a few sticks—it may be a loose bundle of pea rods or a handful of thorns—have been casually left on a plot of grass or weeds during the winter that the vegetation under even that skeletonised form of shelter has in spring—say in February—perhaps grown 2 or 3 inches, and is fresh and green while the unprotected surface is totally destitute of verdancy. If a similar covering is placed over a Radish bed, or any other low crop, the effect of such trifling shelter is equally manifest, and suggests how beneficial even a little shelter may be during the season when every additional degree of heat is valuable and every degree of cold is dangerous. Asparagus tops without the seeds, pea haulms, evergreen boughs, a few leaves, and a little litter where it can be used, are all sheltering aids which are not to be despised; and those who use such aids freely, yet intelligently, are generally the most successful in providing a supply of these requirements which sustain their own credit and win their employers' satisfaction.

But there are plants of a different nature than the above which are individually more valuable, and if destroyed cannot quickly be replaced, which need protection against the excessive severity of the frost. Roses are frequently endangered, and newly-budded and choice sorts should have some protection afforded them. In protecting newly-budded Briars, or Roses that have not large heads, nothing is better, more neat and effectual, and more easily applied than to wrap a hayband round the stocks—for these are as susceptible of injury as the heads—and to envelope the heads in the old straw-bottle envelopes which have been sent from the wine merchant's. These are generally well and closely made, and will last for several years if taken care of. I have collected them for several years until quite a store has accumulated, and it is not too much to say that by their aid I have preserved hundreds of Roses from being killed; the proof being the destruction of many old sorts or plants not greatly valued which have not been covered, and which have succumbed to the intense frost, while those which have had the protection have passed through the winters in safety. When the Roses are thus encased they have a snug comfortable appearance which is not at all unsightly—in fact the utility of the coverings is so manifest that they almost appear attractive, which they certainly are to the employer for whom I have grown and protected Roses for several years. If these envelopes are not to hand from the wine cellar it is not difficult to make some after the same fashion which will answer the purpose equally well, although they may not be so artistically made. The same mode of enveloping dwarf Roses should be adopted whenever there is danger of their being destroyed by the frost; neat cones made of straight-drawn straws are not unsightly, and are effective. Air can be admitted on any side according to the weather, and to prevent—which is very important—the buds swelling into growth before their proper time.

The same mode can be adopted in protecting tender plants and Conifers on lawns. A framework of stakes arranged round each specimen, and laced with common cord as a foundation for the envelope of straw, and a few more outer cords to keep the straw in its place, is all that is needed: the protection is complete, and the cost trifling. Plants on walls, as Myrtles, Chimonanthus, Figs, Roses, &c., should have coverings of mats or straw, or both if needed; or by lack of an hour's work in this matter given at the proper time a wall bare of flowers will have to be endured, which will take, it may be, years to cover as before.

But while the work of covering is important, so also is that of uncovering. The work must be done gradually and at the proper time. There must be no forgetfulness and a sudden tearing away of the protection on finding that it has been permitted to remain too long. It must not remain too long, for that is an abuse of a practice which if properly used is not only beneficial, but in many cases and districts is absolutely necessary. The necessity of protecting plants which are liable to injury, and of sheltering simple yet important crops, is too often admitted at the wrong end of the season. That is just after the injury is done instead of just before, that I am induced

to record my practice, in the hope that it may yet be in time to serve some useful purpose.—A NORTHERN GARDENER.

#### REPORT ON ONIONS GROWN AT CHISWICK FOR TRIAL BY THE FRUIT AND VEGETABLE COMMITTEE OF THE ROYAL HORTICULTURAL SOCIETY, 1875.

THE seed for this trial was furnished by the following gentlemen—viz., Messrs. Barr & Sugden; Messrs. Carter & Co.; Messrs. Cutbush & Son; Messrs. Bessy, Belfort; Messrs. Nutting & Son; Messrs. Sutton & Sons; Messrs. Veitch and Sons; Messrs. Vilmorin & Co., Paris; Messrs. Harrison and Sons; Messrs. Stuart & Main; Messrs. Piccirillo; Messrs. Hovey & Co., Boston; Mr. Dancer, Mr. J. Perry, Mr. A. Parsons, Mr. R. Dean.

The seed was sown on March 16th in well-pulverised moderately rich soil, which had the previous season been well manured for Celery. The season was on the whole favourable for the growth of Onions, so that the trial was so far of a very satisfactory character. Altogether 155 samples were sown, representing ninety-eight different names, of which number twenty are here described as quite distinct.

The report only extends to those varieties which have been proved to be well adapted for spring sowing and early autumn or winter use, the remainder of the Tripoli and Silver-skinned sections being again submitted for trial as autumn-sown Onions.

1. **WHITE SPANISH** (*synonyms*, Banbury (Perry), Banbury Improved, Nuneham Park, Improved Nuneham Park, Reading, Improved Reading, Naseby Mammoth (Carter & Co.), Oxonian Prize (Nutting & Son), Cutbush's Al (Cutbush & Sons), Portugal, Castello's Prize (Waite, Burnell & Co.).—This variety is the one most generally cultivated. The plant is of free growth, the neck of medium size, and ripens off early and well. The bulbs are large, a fair-sized specimen measuring about 12 inches in circumference, and from 2 to 2½ inches in thickness. The shape is flattened, the base broad, flat, frequently a little hollowed and uneven, somewhat globular towards the stalk in the best forms. Skin pale straw, falling off readily and exposing the pale greenish-yellow outer flesh. The flesh itself is firm and solid, almost white, and of excellent quality. This variety keeps generally in good condition up to the month of March. The Banbury and Nuneham Park types were the most approved.

2. **LARGE STRAW-COLOURED** (Vilmorin) (*syn.*, Yellow Flat (Hovey & Co.)).—This is only to be distinguished from the White Spanish by the darker colouring of the outer skins.

\* **Yellow Leucure** (Vilmorin), **Yellow Cambrai** (Vilmorin).—These were considered very spurious stocks of the Large Straw-coloured.

3. **WHITE GLOBE**.—Plant of free growth, forming in general a small neck; ripens off early and well. The bulbs are of medium size, from 9 to 10 inches in circumference, and about 2½ inches in depth. The shape is somewhat globular or obovate, with a finely rounded high crown. The skin is pale straw like the White Spanish, and it is, indeed, similar to that variety in every other respect but its more globular form. It is an excellent keeping sort, and much esteemed.

**White Intermediate**, **Oscar** (Cutbush & Sons).—These are mixed and indifferent stocks of White Globe and White Spanish.

4. **TANNONS** (Vilmorin et Cie., Stuart & Main).—Plant of free growth but somewhat tender, succeeding best in a warm season. Neck somewhat gross. The bulbs are of very large size—about 13 inches in circumference, and from 8 to 8½ inches in depth. The shape is obovate, the base somewhat broad and flat, whilst the top tapers more to the stalk or neck. The skin is pale straw, and peels off readily like the White Spanish. The flesh is pale and rather soft and flabby, but of mild and excellent quality. This is a very large and handsome Onion for early autumn use. It does not keep well, and generally begins to shoot before Christmas. It bears a close resemblance to the Imported Spanish Onions.

5. **YELLOW DANVERS** (Hovey & Co., Vilmorin et Cie., Carter and Co.) (*syn.*, Danvers Yellow).—This is a very fine and distinct Onion. The plant is of free growth, the top slender, of a rather pale green colour, and with a very fine slender neck, so that it ripens off well. The bulbs are of medium but very even and regular size, from 10 to 11 inches in circumference, and about 2½ inches in depth. The shape is roundish globular, very regular, with a small base and a small neck. The skin is of a dark straw colour, the outer coating peeling off freely but

not exposing the flesh. The inner coating remaining firm, giving the Onion a very neat, clean appearance. The flesh is very firm and solid throughout, and of fine quality. A splendid keeping variety.

**New German** (Veitch & Sons).—This bears a close resemblance to Danvers Yellow, but scarcely appears to keep so well.

**6. BROWN GLOBE** [*syn.*, James's Keeping].—This is of the same character as the White Globe, but having darker or reddish brown skins; some are pale-fleshed throughout; others, these being the darker-skinned, have a slight shading of red as an outside coating of the various layers as in the Red varieties. It is an excellent keeping variety and much esteemed. The James's Keeping of some is more flattened near the crown, forming a sort of shoulder to the stalk, and of others again it is similar to the Pear-shaped.

**Magnum Bonum** (A. Parsons) is a very fine selection of the Brown Globe.

**Brown Intermediate. Bedfordshire Champion**.—These are mixed stocks of Brown and White Globe.

**7. PEAN-SHAPED** [*syn.*, Pyriforme].—This is allied to the Globe section, and may be described as an elongated form of that variety. The plant is of free growth, the great majority producing very thick necks with very little bulb, so that they do not ripen off well. The true form is like that of a long Pear tapering mostly towards the stalk from 7 to 8 inches in circumference, and from 4 to 5 inches in depth or height. The skin is of a dark reddish brown, and falls off readily. The flesh is moderately firm and solid, but it is not a very good keeping sort, and its shape does not recommend it. A good selection of this is sometimes sent out as James's Keeping.

**8. DEPTFORD** [*syns.*, Brown Spanish, Improved Brown Spanish, Strasburgh, Strasburgh Dutch, Pale Red Niorste, Light Red Strasburgh].—Plant of free growth and very hardy, forming a small neck and ripening early. The bulbs are of medium size, flattened or oblate, of pretty even and regular form. The skin is of a dark reddish-brown colour. The flesh firm, solid, tinged with red. An excellent keeping variety.

**9. FRENCH STRASBURG** [*syn.*, Pale Red St. Brisux].—This is distinct from the Deptford or English Strasburg. The bulbs are smaller, of very uneven shape, and frequently split open into several crowns. They are of a dull reddish colour. Altogether very inferior varieties of the Deptford class.

**10. DEEP BLOOD RED**.—Plant of free and hardy growth. Bulbs of medium or rather small size, flattened or oblate, and generally of very even and regular form. The outer skin is of a dull red colour; the inner coating of a deep glossy red. The flesh itself is pure white, it being only the outside coating of the various layers that are coloured, and these become paler towards the centre. It is very firm and solid throughout. This is the strongest-flavoured Onion, and the latest keeper. On these accounts it is a valued variety.

**Blood Red**.—This is simply a paler-skinned variety of the preceding, and the most common.

**11. WETHERSFIELD RED** (Hovey & Co., Carter & Co., Benary and Son) [*syn.*, Bright Red Mexieres (Vilmorin)].—Plant of free and robust growth. The neck small, ripens off freely. Bulbs large, flattened or oblate, very even and regularly formed, about 12 inches in circumference and 2 inches in depth. The outer skin is of a light dull red colour, and peels off freely; the inner coating being light purplish, shading greatly from the crown to the base, where it is very pale. The flesh is pure white, the outer surface of the coating only being coloured. It is very firm, solid, and of mild and excellent quality, and keeps well. A remarkably fine and handsome Onion from America. The finest type of Red Onion.

**12. EARLY RED** (Hovey & Co.).—This is a rather early red variety. The bulbs are of medium size, flat, of a very dull red colour. The flesh is firm and solid, and of good quality. It showed a tendency to the production of several crowns, which burst and spoil the bulbs, and prevent them keeping.

**13. TWO-BLADED**.—This name is given to denote its peculiarity of only producing two blades or leaves. These form small bulbs very early in the season, and soon ripen off. A great majority, however, grow into larger bulbs, and these have the ordinary number of leaves. The true two-leaved type has small roundish bulbs about an inch in diameter. The skin is of a dull-yellowish brown colour; the flesh greenish white and frequently a little coloured. They are very firm and solid, and keep well. The small size makes it useful for pickling purposes.

**14. TENNESSEE** (Benary & Son).—This greatly resembled in appearance the smaller types of the Two-bladed.

**15. SILVER-SKIN** (Nutting & Son) [*syns.*, Silver-skin Pickling (Veitch), Early White Silver-skinned (Benary & Son), White Round Early Hard Dutch (Vilmorin et al.)].—The bulbs are of medium size, roundish oblate; a great many are apt to split open. The outer skin is pure white or silvery, peeling off freely and exposing the next coating, which is white with green veinings. The flesh is pure white, exceedingly firm and solid. Keeps remarkably well, and is useful to those who prefer very white Onions. This is quite distinct from the Paris Silver-skin, which does not keep well.

**16. QUEEN** [*syns.*, New Queen, Piccirillo's New Queen].—This is a very small and very early variety of the Silver-skinned section. It forms bulbs almost as quickly as a Radish, and has rarely more than two or three leaves. They were fully grown last season by the 1st of June, about fifteen days earlier than the White Italian Tripoli, which variety in the late trial it most nearly resembled. Many large and later-growing examples were observed in each sample, which, if the seed was not mixed, implies a tendency to deterioration. In this, as in other respects, it exactly resembles the Nocera as introduced from Italy about thirty years ago, and the Florence White of earlier date.

**N.B.**—All the section of Silver-skinned Onions, including the Queen, White Italian Tripoli, Marzajola, Nocera, Paris Silver-skin, Early White Naples, and White Lisbon, also the Giant Tripoli section, including the Giant Rocca, Red Sallow, Madeira, &c., which are found valueless as spring-sown varieties, will form the subject of a separate report when their respective merits have been tested as autumn or winter-sown Onions.

**17. POTATO ONION** [*syn.*, Underground Onion].—This is not propagated by seeds. The small bulbs are planted in the ground like Shallots, and around these a number of new bulbs are produced. These bulbs are of average size, of somewhat irregular shape. The skin reddish brown, hanging very loosely. The flesh is tolerably firm and solid, and of fair quality. It does not keep well, but is useful for procuring an early supply of Onions.

**18. EGYPTIAN** [*syns.*, Egyptian Bulbiferous, Tree Onion, Garden Rocamboles].—This variety when planted throws up a stem on which, instead of flowers, small bulbs are produced of above the size of small marbles, which are very excellent for pickling. It is propagated by planting these bulbules (the largest of which will bear bulbs the same season), or by the bulbs which are formed in the ground, and which have not formed stems.

**19. AMERICAN PERENNIAL TREE, or TOP ONION** (Carter & Co.).—This produces small bulbules in the same manner as the Egyptian Bulbiferous, but of a much smaller and inferior character. No bulbs are formed in the ground. The plant is perennial; the roots are long and fibrous.

**20. WELSH**.—Of this there are two varieties, the Red and the Green. The plant is an herbaceous perennial, and forms no bulbs; the roots are long and fibrous. The green tops or leaves only are used. It may be propagated by seed or by division of the roots.—A. F. BARRON.

## GREENHOUSE HEATING FROM A KITCHEN BOILER.

SOME weeks since it was attempted to be shown in our Journal that greenhouse heating from kitchen boilers is impracticable, if not positively dangerous. Having had an apparatus working perfectly for eighteen months I will endeavour to describe it for the information of your readers, and recommend it as being an economical arrangement.

In a yard next an underground kitchen is a Fern stove; in the opposite corner, distant 80 feet, is a bath room, both of which are heated by hot water without any extra cost or labour. From the top of the boiler which is fixed in the back of the kitchen fireplace, but with a flue under and up behind, a 2-inch metal pipe is carried to the stove, round which the water circulates in a double coil of 4-inch pipes, thence across the yard in 2-inch, round the bath room in 4-inch, recrosses the yard in 2-inch direct to the boiler, which it enters about a foot from the top. A leaden pipe leads from the boiler to the bath; from this pipe a short branch supplies the wash-basin.

The cold water is supplied by a 1-inch pipe from the w.c. cistern above the bath room; into this cistern a blow-off pipe

from the boiler discharges the waste and steam. With this arrangement an explosion is impossible. The cold-water feed-pipe, being conducted inside my dwelling house, it cannot freeze; and the reserve water in the cistern is a sufficient supply for several days should the water company's supply fail.—  
W. J. TAYLOR, *Rye Hill, Newcastle-on-Tyne.*

## ROYAL HORTICULTURAL SOCIETY.

DECEMBER 9TH.

A SPECIAL General Meeting of the Royal Horticultural Society was held last Thursday afternoon in the Council Room, South Kensington, under the presidency of Lord Aberdare, "for the purpose of explaining the scheme of the Council, and of giving the Fellows an opportunity of stating their opinion on its details." The importance of the meeting can be estimated by the fact that the following notice was attached to the advertisement calling the meeting:—"The President trusts that it will be convenient for Fellows to attend, as the subject to be discussed is of the utmost importance to the interests of the Society." In response to that invitation there was a large gathering of the Fellows, several ladies being present; and it may be stated that in the conduct of the proceedings by those who took part in them there was an almost entire absence of that bitterness of feeling and expression of jealousy which for the last few years has characterized the meetings of the Society. At the Council Board the President was supported by the Hon. and Rev. J. T. Boscawen, Admiral Hornby, Mr. Grote, Mr. Little, Mr. W. Haughton, Dr. Denny, Mr. Warner, Mr. Camplon, Mr. Henry Webb (Treasurer), and Dr. Hogg (Secretary). Amongst the general body of the Fellows were the Earl of Strathmore, Viscount Cardwell, Viscount Bury, Lord Alfred Churcill, Sir Peter Pole, Sir Alfred Blad, General Scott, Dr. Pinches, Mr. Eiggins, Mr. Guedalla, Mr. Bowen, Mr. Shepherd, Mr. Steward, Col. Trevor Clarke, Mr. Bateman, Mr. W. H. Jacob, Mr. Knill, Mr. Caird, Mr. Godson, sen., Mr. Godson, jun., &c.

The ASSISTANT SECRETARY having read the advertisement convening the meeting, the noble

PRESIDENT rose and said:—Ladies and Gentlemen, it is almost a necessary consequence of the last general meeting, held on the 19th of August, that this meeting should be called. On the occasion I refer to you were informed that an arrangement, which I think I may call a satisfactory one, was being made with the Commissioners of the Exhibition of 1881, and with respect to which the Commissioners showed considerable spirit, and it was submitted for your acceptance. It was, I believe, all but unanimously accepted, and then it became the duty of the Council to give effect to it. I will not trouble you by going over again the familiar ground of the arrangements and the negotiations with the Commissioners, I will assume you are acquainted with them; but there is one of them of the very highest interest, and on which the Council felt there was needed immediate attention, and that was the condition of raising the income of the Society to £10,000 a-year. That was agreed upon in order to maintain the effectiveness of the gardens, because unless you sow you cannot reap [hear, hear], and so unless you keep the gardens in a good condition it is impossible to expect that you will have numerous subscribers [hear, hear]. I have no doubt you have by you the annual financial statement, and you will see by it that a larger sum than £10,000 has been received, but it was received from exhibitions, which we could not take into consideration. What I am really dealing with now is the item of subscriptions, and this is a matter which causes us great anxiety, and in a short statement I will show you the necessity for taking strong measures—very decisive measures, to arrange this matter with the Commissioners. The receipts from annual subscriptions in 1873 were £8194, and the subscribers were composed of 870 old and 524 new subscribers; but the number fell in 1874 to 725, leaving a deficit of a considerable number on the year. In the meantime the exhibitions largely increased the income, and I will just state to you that while in 1867 the receipts were £1402, in 1874 they were £698, and last year £805. Now last year was, unfortunately, an exceptional one in two respects: The shows were remarkably good, but the days on which the principal shows fell were exceptionally rainy, and the receipts of the Society show how much the success of the shows depends upon the weather. Still I am told that in this Society, from constant change of management, there has arisen a want of confidence and a withdrawal of many of the exhibitors, and the consequence of this has been that the Society has lost its old reputation, and it possibly will take some time before the old confidence can be restored. The Council, then, having this state of things before them, and having also before them the necessity of providing within three years an increase in the income of the Society of £3500, it became the consideration of the Council by what means this could be done. I am unable to speak myself with any absolute confidence, or rather authority, upon many matters in connection with the affairs of the Society, because almost the only recommendation I possess

is that I have never mixed myself up with the disputes which have unfortunately taken place in the Society [hear, hear, and laughter]. I have paid my subscriptions steadily, and I have given my allegiance to the "powers that be," but without entering into the nature of the differences existing between them and the Fellows of the Society. Coming, therefore, upon the Council without being prepared with any previous opinion on these subjects, I have been enabled to listen to and benefit by the experience of those who were upon the Council, and I found it is almost their unanimous opinion that in many cases the reason why the receipts of the Society did not increase in proportion to the increasing love of horticulture and the increase of population in this neighbourhood, that in point of fact the great cause was—the main cause was—the great abuse of the power of transferring tickets [loud cries of "hear," and a voice "no"]. No doubt that was a valuable privilege, and one which the holders of these tickets greatly valued; but I think you will agree with me that when they were made the means of enabling householders and their families to dispense with getting, as they ought to have got, their annual tickets for the gardens, I am sure the experience of many of you will tell you there are many families who enjoy as fully as they can the advantages of the gardens who never contribute a single sixpence towards their maintenance [cheers]. It was necessary this abuse should be stopped [hear, hear], and you know it is very difficult to prevent or to stop an abuse without causing inconvenience. The Council were well aware that if they attempted to stop this abuse they would cause dissatisfaction, and I frankly admit that the Council felt that unless the Fellows made certain sacrifices of their privileges we could not secure united action in the Society, and more than that, that we could not improve the financial position of the Society. And so we have now come to you to make this statement, and we hope you are prepared to make these sacrifices in order to prevent the loss of these beautiful gardens. You see that I attach the utmost importance to the results of the present meeting. If you come to any weak resolution this day—if the Council do not receive the support of this meeting, not necessarily binding them to all the details of this scheme, I think we may say the days of the Royal Horticultural Society, so far as South Kensington is concerned, are numbered ["no" and "hear"]. Now you have before you a scheme prepared by the Council, which I am sure all of you have read and studied [published in No. 793 of this Journal, Nov. 4th, page 400]. I have read a great number of letters, nearly all of them giving a fair, candid, and temperate view of the matter. Some are critical, but not a very inconsiderable number have approved of the scheme. Others criticize it, and they are the majority; and in some cases we have had suggested the substitution of other schemes of the writers. Now, I believe with the Council that they are right in putting forward to you what they think is right, and that it would be wrong if they did not give you the opportunity of expressing your opinions, and enable you to form a fair judgment as regards what the object is, whether the scheme of the Council or those proposed by any Fellows among you ought to be accepted. Should there be a very distinct opinion of the majority of the Fellows on the subject I am prepared to say, as far as the Council are concerned, they will give to their representations the fullest and fairest consideration [cheers]. What we want to do is to take the necessary measures, which we believe we cannot do without, and whether they should go to the extent which we propose it is for you to judge. I should not say we would not accept any amendment you may consider necessary, but having carefully considered the subject you must be prepared to say what you will do. The strongest objections to this scheme have come from those who are compounders. I cannot see on what grounds their opinions rest so far as regards the period since 1865. I cannot see, with respect to those who compounded with a knowledge of the bye-laws, what legal right they have to complain of any action which had become a necessity. But whether they have a legal right or not, or a moral right, I think when men have purchased certain privileges and advantages, and paid a sum down for them, they should be the last men to do anything unfair or harsh without the strongest reason. We also say, in considering their case, it would be the bounden duty of the Council to listen to anything which might relieve the compounders of their disabilities, and we are prepared hereafter to inflict upon them nothing that can be shown not to be actually necessary [hear, hear]. But when I tell you the number of those who have compounded is very nearly half of the subscribers you will see the difficulty which makes it altogether impossible to accept the life-compounders without great loss. The number of life-compounders is 525, and the number of annual subscribers is 1184. If the life-compounders are to be left in full possession of their rights it will be impossible to get the residents in the neighbourhood to become annual subscribers. In that case we shall not be able to raise the necessary funds, and the result will be that in the attempt to save everything we must necessarily lose. We therefore call upon them to take a part in the sacrifices which must be made, and if they think we call upon them to do too much, let them

make their suggestions. I entreat them not to stand upon their moral rights, but to come forward in the general good and tell us what sacrifice they are prepared to make [hear, hear, and applause]. Of course in any measures we take will be included a house-to-house visitation [hear, hear], in a strong attempt to make all those who use the gardens to subscribe to them, and it may be hereafter possible—and it will be a great pleasure to the Council if it is so—to restore some of the privileges we call upon you to give up [hear, hear]. It is impossible to disguise that one of the many difficulties which have encumbered our action is a divided counsel amongst the Fellows [hear, hear]. We know such a thing has existed, and that there does exist considerable jealousy between the local subscribers and those who are specially connected with scientific horticulture. I do hope they will proceed in this matter without any such feeling, because if they do not it will bring about the coming disaster. On an occasion of this sort which I feel is, as far as the interests of this Society are concerned, a solemn one, I think it my duty to tell you under what circumstances the Royal Horticultural Society was invested with the management of the gardens. The spokesman of the Royal Horticultural Society was Dr. Lindley, one of the most eminent botanists this country has produced—one of the men who most had, of all others, the interest of science at heart, and one of those who would not degrade the study of science; and let me read you the opinions he expressed at the opening of the Horticultural Society. Dr. Lindley said—"We, the Council of the Royal Horticultural Society, venture to congratulate your Royal Highness upon the important stage at which we have now arrived, in which you take so active an interest—an undertaking for the establishment at the west end of this metropolis of a noble garden by which, with the aid of Chiswick, not only the science of horticulture will be promoted, but an additional means of enjoyment and recreation afforded to the dense population of the neighbourhood."

A FELLOW.—What is the date of that?

THE PRESIDENT.—It was in 1861, on the occasion of these gardens being handed over to the Horticultural Society. You see Dr. Lindley was not without taking into account the enjoyment and recreation of the members of the dense population around these gardens [hear, hear]. I know many of you look with a longing look to Chiswick Gardens [cries of "hear"]. Well, "Distance lends enchantment to the view" [laughter]. Those were considered as the good halcyon days when those who promoted the study of horticulture wished to do so without the influence and chatter which they now have to cope with ["hear, hear," from a Fellow]. The cheer of the honourable gentleman is a confirmation of what I say as to what their views were [hear, hear]. Well, we had to struggle with difficulties not greater than these which may be overcome, but really there is little strength in the suggestion that our connection with South Kensington is an unfortunate one. In 1804 the Society was formed, and in 1809 it received its charter. In 1890 it got into such difficulties that a committee was appointed to inquire into the question of its management, and the committee reported that then there existed a debt to the extent of £20,848. Fortunately, two years afterwards the plan of annual exhibitions was started. At first it was but a small success, but afterwards it became a great one. Between 1832 and 1841, assisted by the use of the Duke of Devonshire's gardens [hear, hear], the Society was able to pay off some of what it owed. In 1855 they were again oppressed with the amount of their debt, and in 1856 so hopeless was the condition of the Horticultural Society that the abandonment of Chiswick was considered and actually proposed. In 1858, in spite of several vigorous efforts made to pay off the debt, it had increased very largely, and the Society was put to the resource of putting up their magnificent library to auction, and it brought some £900. In 1861 a proposal was made to the Society to take charge of these gardens. The number of Fellows rose from 958 at that time to 8360 in 1864 [cheers], and they were enabled to pay off the sum of £10,000 with which they were encumbered. I think, therefore, it cannot be shown that the connection with South Kensington was, in a financial point, a disastrous one, and I decline altogether to believe that when something has been done to create a love of horticulture it is inevitable that something should occur not pleasing to the lovers of the science. The great desire of the late Prince Consort was not only to popularise the love of horticulture by the establishment of beautiful gardens in the metropolis, but, as he himself said, to connect it with architecture, sculpture, and painting [hear, hear]. To some extent his desire has been realised. The Commissioners of 1851 have spent no less than £63,000 in the architectural adornment of the gardens, with a taste and beauty acknowledged everywhere. In the neighbourhood are rising structures to contain portions of the collections in the British Museum. Indeed, the best—the very best specimens of European art are to be found in the South Kensington Museum, so that the local and excellent plans of the Prince Consort to establish a local place for arts and science have not altogether been disappointed [applause]. I do trust the measures taken to-day will secure the success of that scheme; and

in order that we may act unitedly we will listen to whatever objections may be urged against our scheme with attention, and incorporate whatever amendments or suggestions that may be found not wholly inconsistent with them, and in saying that the Council feel assured they will receive the friendly support of those who do us the honour of attending on this day [prolonged cheers].

Dr. PINCHES said the Fellows must congratulate the noble Chairman on his statement respecting the past history and present position of the Society. He wished, however, he could congratulate the Fellows upon the fact that they had fallen upon the philosopher's stone. They wanted to find some method to raise their income from £7600 to £10,000 per annum, and only on this condition that they should enjoy the privileges they possessed for many years past [hear, hear]. He thought the object they had in view was not restricted to this or that group of Fellows, but one in which all the Fellows were equally interested—he meant the prosperity and continuance of the Royal Horticultural Society [hear, hear]; and if they differed in their views as to the best way of effecting their common object, he hoped they should do so in the same courteous friendly spirit which the noble Chairman had maintained [cheers]. Speaking for himself he (Dr. Pinches) might say he had had no conversation with any of the officials of the Society, or with any of the Fellows of the Society except one, on the matter before them as to the new conditions or privileges, and in the remarks he was making was speaking for himself only. He must say when he read the instructions which he received, and saw it stated that the reason why their subscriptions were so much reduced was on account of the system of transfer, he did expect some other solution of the difficulty than that proposed [hear, hear]. The question, no doubt, was full of difficulty, and it was no wonder the Council had not hit upon the happiest method of raising the fortunes of the Society. He thought they had not done so [hear, hear]. It would have been better if the Council had called a meeting and said to the Fellows, "These are the changes we propose, and we ask you to sanction them" [hear, hear]. It would have been better for them to do that than to issue a printed paper which they were practically compelled to withdraw ["no" and "hear"]. He thought the sacrifices the Fellows were called upon to make were too great—much greater indeed than was necessary, and which, even if conceded, would fail to accomplish the object they all had at heart [applause]. Now, he should give to the meeting a comparison of the privileges the Fellows did enjoy at present and those they should enjoy under the proposed regulations. A four-guinea Fellow—and he was sorry to hear that class of Fellows only numbered 1100—had now two tickets, both of which were transferable, and the two together enabled him to bring four other persons, so that he had admission for six persons on all occasions except those of flower shows. In addition to that he had the privilege of giving away forty tickets of admission in the year—a privilege which, estimated by the number of tickets, is not much used. He was quite willing to concede that these tickets should no longer be issued [hear, hear]. But what were they offered in place of them? They were offered one ticket for their four guineas which was not transferable, personal admission being only granted. But they might have two more tickets, and put on them the names of the persons to use them, so that they would have three admissions instead of six, and only one of the three could be transferable under any circumstances whatever.

A FELLOW.—No, no.

Dr. PINCHES.—If I am wrong, please correct me. That, as he understood it, was the existing state of things. Furthermore, if a gentleman was a four-guinea Fellow there were certain days—"reserved days"—on which positively he could not bring in either of his nominees or his own wife.

Sir ALFRED SLADE.—Hear, hear.

Dr. PINCHES felt sure the Council had never contemplated that. If a man wanted to enjoy his privileges he must pay eight guineas a year. There was a mysterious allusion to "reserved days" in the document issued by the Council. He did not know what those days meant, but he should say it would be a very difficult matter for the Council to shut the gardens in the face of the Fellows by any regulations on which they might agree [hear, hear]. He might be wrong, and no doubt if he was the legal adviser of the Society would correct him. Then they were to have the privilege of having a book of tickets—twenty tickets for a guinea. That was the only feature in the new propositions worthy the serious consideration of the Fellows [oh!]. He thought it should be made a condition that on Saturdays the gardens should be kept as a promenade for the Fellows. It seemed to him that if, with all the attractions they had been enabled to offer the Fellows in past years—including tickets for the International Exhibitions—they had failed to attract to them a large number of Fellows and so raise the income of the Society, it was only a natural consequence that if they abridged the privileges of the Fellows they must abridge the number of those who would go to the gardens [cheers]. The thing was palpable and required no further

consideration [hear and no]. He was not surprised to hear, although he much regretted it, that a considerable number of Fellows had stated their intention to withdraw from the Society if those propositions were gone on with. He should be glad to hear from any member of the Council what it was they held out to those who were likely to become Fellows. If they failed to attract them when they offered admission for six, what would be the result when they only gave them admissions for three? [hear, hear.] He should like to arrive at a practical issue on this question, but would not embarrass the Council by any attempt to move a resolution or amendment to the propositions. He should, however, call attention to one or two points in the old rules and in the new ones, and possibly the suggestions he would make might be adopted. He was very reluctant to embarrass the Executive of the Society, and he would just suggest that this might be done—to retain Rule 1 of the old rules and that in Rules 2 and 17—

Mr. GOSLOW, sen.—I rise to order. If you don't move a resolution you have no right to speak ["oh, oh"].

Dr. PINCHES.—I have no objection to move a resolution to put myself in form.

The PRESIDENT.—Surely any observations upon this matter in which we are all so interested can be made without moving a resolution [cheers].

Dr. PINCHES said if it were necessary he could easily move a resolution. He would suggest that the privilege be retained [cries of "Read"]. Well, it entitled the Fellow to two transferable tickets, and gave admission both to Chiswick and South Kensington. Then in Rule 2, which gave the right of admitting two friends on any day in the week, he thought they might substitute "one" for "two" [hear, hear], to show they were anxious to help the Council out of a difficulty. He suggested that in Rule 17 the word "two," which affected two-guinea Fellows, should be taken out, and the word "one" let in. He should propose that in the new propositions privileges 3 and 5 be adopted—that was as regarded purchasing tickets for households; and the rule respecting the restriction upon Fellows bringing in their wives any time be amended. No. 6, to admit by personal introduction, should be abandoned; and he further suggested that it might be possible in future to charge all new Fellows five guineas for what they called the double ticket and three guineas for the single ticket. These were the suggestions which occurred to him, and he should not trespass further on the time of the meeting. He should move a resolution towards the close of the meeting.

Lord BURY said he did not propose, in discussing this matter, to enter into any such details as those referred to by the last speaker. No doubt the last speaker was quite right in his examination of this scheme. First, he (Lord Bury) asked to be permitted to congratulate the Society that his successor in the presidential chair was a gentleman so highly respected and so competent to deal with the complicated affairs of the Society as his lordship [cheers]. They were all extremely fortunate in securing the services of his lordship, and he must say that having a vivid recollection of the very hard work that has to be done as President, they had reason to think themselves lucky in the selection of President which had been made [applause]. In his lordship's opening speech he did not exactly tell the meeting what he wished them to do. His lordship said he only invited discussion on the scheme of the Council, and that the Council intended to be influenced by the decision the meeting would arrive at. He (Lord Bury) wished now to tender his services to his noble friend and the Council in carrying out any scheme which might be decided on; and in order to do that with effect the best way was to criticise frankly, and not with any opposition or hostility, the scheme submitted to them [hear, hear]. The scheme emanated from a Council which turned out the Council of which he (Lord Bury) was President.

The PRESIDENT.—No.

Several FELLOWS.—Oh, yes.

Lord BURY went on to say he should not make any observation which would impart any unpleasant character to their proceedings; but he dared say he should have been in the presidential chair if the Society did not wish to dispense with his services, and the reason why the old Council was displaced by the present one was that the element which his friend Lord Abderast called the "scientific horticultural" element was in the persons of the late Council somewhat disregarded. Now they had the gardeners in the ascendant. They had produced their scheme, and it seemed to him the only point on which they were at all agreed was that the income of the Society was unsatisfactory [hear, hear]. Now the scheme was before them as to the manner in which that state of things was to be remedied. And what did it all amount to? Why, that the privileges hereafter enjoyed by the Fellows were to be very materially curtailed. As they could not offer sufficient attractions in the gardens in the old days when the Fellows had many privileges, he did not see how they could raise the income by diminishing the attractions [hear, hear].

The PRESIDENT.—Lord Bury ought to remember he is repeat-

ing the arguments of the last speaker [hear, hear]. We have no such wild scheme in our minds as that of saving the Society by reducing the privileges of the Fellows. What we want is to prevent an abuse [cheers]. I am, at the same time, quite sure that Lord Bury will grapple manfully with the scheme, and in doing so will not remember former disputes.

Lord BURY was perfectly willing to accept the courtesy of his noble friend, but he would not exactly admit the charge of abuse of privileges by the old Fellows. His noble friend in the chair appeared to think he would be able by the scheme of the Council to bring a large number of new subscribers, and in so thinking he (Lord Bury) deferred to his noble friend, but he did not think the scheme submitted by the Council was one which would find general favour throughout the Society [hear, hear]. His noble friend referred to the first origin of the Society. It appeared there were at first some nine hundred Fellows, and that in two or three years the number raised to 8500. What did that prove? Why, that the attractions of the gardens brought the Fellows, and that they were still in possession of these gardens, and that it was the possession of these gardens which enabled the Society to pay their way. The Council of which he (Lord Bury) was a member submitted a scheme to the Society which, if accepted, would have enabled them to go on perfectly well—that was, that the Society should revert to their original possessions before they came to South Kensington. He thought if the Society went back to Chiswick very much better work would be done for horticulture. It would not hamper the Council, and would allow the local Fellows to make such terms as they could with the Commissioners. It would keep these gardens open as one of the lungs of the metropolis, and bring a large accession of horticultural Fellows. People joined this Society in order to be in possession of those magnificent gardens, to have a breath of fresh air, and keep the place open as one of the lungs of the metropolis, and that was what he said, if not hampered in the future, the horticultural element would still be able to do. He thought horticulture would be the better if the Society had adopted the plan which had been proposed, and if they did so they would not—that is, his friends and himself, be in a minority, and the scheme would be amply sufficient to carry the Society on. He distinctly said that even if it was found impossible for the Society to keep these gardens, it would still be impossible for the Commissioners to build over this open space [hear, hear]. He asserted that it would still be kept as an open space even if the Society went to the dogs [hear and laughter]. Why, he asked, should the Society be told that if they did not agree to the plan of the Council the Society would be swamped? Why, what could happen if even that occurred? Why, even if the Society was swamped it would be no worse than it was at the present time [hear, hear]. With respect to the differences of the Society, he and the other members had kept an absolute neutrality [hear, hear]. His friends and his supporters thought, and he believed they would always think, that by the propositions of the Fellows they were hardly dealt with [hear, hear]. The local Fellows, he thought, were hardly dealt with. What he stated distinctly and unreservedly was that the gardens of South Kensington could not and would not, being one of the lungs of the metropolis, be closed to its people [cheers]. In fine, his comments amounted to this, and to this only, that he thought if the proposals of the Council were carried out they would bring upon the Society a worse position than it occupied before [hear and cheers]. In conclusion, Lord Bury expressed his opinion that his noble friend in the chair had really the interest of the Society at heart, and said he felt certain that his noble friend would not be a party to any scheme which he did not think was calculated to promote the interests of horticulture and of the Society which took its name from that of the science [cheers]. At any rate, by the aid of the local Fellows the Society would not have the slightest difficulty in keeping the gardens as being one of the lungs of the metropolis [cheers]. He thought that if the propositions of the Council were carried out they would place the Society in a worse position than that in which it at present stood [cries of "no"]. In conclusion, Lord Bury entreated the Fellows to revert to the proposals put forward by the Council of which he had been the last president [cheers].

Sir PETER POLK said, amid a good deal of laughter, My Lord, four subscribers told me that if these propositions are carried by the meeting they will have their names scratched out of the books of the Society [great laughter].

The PRESIDENT.—Have you anything else to say on the part of these four subscribers?

Sir PETER POLK.—No, my Lord; that is my only objection [laughter].

The PRESIDENT.—It is one I am certain the Council and the meeting will take into very serious account [great laughter]. What we really have to do to-day you all know is a most serious business. The fate of the Horticultural Society hangs upon it, and I am certain that there is not a gentleman in this room who has not at heart the real welfare, the renewed and permanent prosperity, of the Royal Horticultural Society [cheers].

Mr. GUEDELLA said he wished to observe that the increase of subscribers could be only brought about by increased attractions [loud cries of "hear"]. The great success of the Chiswick Gardens was brought by the splendid breakfasts [great laughter]. Oh, yes, he repeated that it was the breakfasts made the whole thing a success [renewed laughter]. Well, if gentlemen laughed he should like to ask how the Botanical Gardens were made a success? Was it not by the lime light [laughter], yes, and other very great attractions? [hear, hear]. Well, now, they were threatened with an aquarium and other attractions which suited all modern requirements and all the wants of the present very-much-changed state of society [laughter]. Well, then, what should the Royal Horticultural Society do? Should it not, as was generally said and accepted, do if it went into Rome as Rome does? [hear, and dissent]. Now, one of the plans spoken of frequently to the Fellows of the Society was the establishment of a skating rink [cheers]. Well, from what he had heard he had to take rather a melancholy view of the subject [a laugh]. He knew very well that the establishment of a skating rink would be a source of greatly-increased revenue to the Society. Well, had the shows increased? If they had it was on the scale of an Irish increase—an increase the other way [laughter]. Respecting the privileges of the Fellows, no doubt there were many, and, as far as they went, valuable ones, but there could be no doubt that there was a very considerable difference of opinion with respect to the new resolutions which the Council had proposed [cheers, and cries of "no"]. The chief thing spoken of by the noble lord in the chair was the abuse of entrance fees, or rather the abuse of transferable tickets, and he (Mr. Guedalla) did not believe that a curtailment of this privilege would bring about a decrease of the abuse if it existed [hear, hear]. His own experience was that with respect to this matter he had not used orders at all. Indeed he had carefully avoided making use of the privilege [hear, hear]. In conclusion of his speech Mr. Guedalla asked the members to be united—to act with one aim and object—the promotion of horticulture and the continued and improved existence of the Royal Horticultural Society, and he emphatically stated that if this were done petty and miserable jealousies and differences would sink, and the Society become, what it was not now, a great national institution [loud cheers].

LORD ALFRED CHURCHILL said he felt very much indebted to his noble friend in the chair for the observations he had made, but he wished to say he did not think the Council would be able to raise by their scheme the income of the Society, and neither did he think that the proposals of the Council were applicable to the great majority of the Fellows. He did not go with the Council that there had been an abuse in the transfer of tickets [loud cries of "hear," and counter cries of "yes"]. If the Council would not treat the Society in a liberal manner, by all means let the Fellows pay for what they got, but let the Fellows at the same time maintain their privileges, and have the power to transfer tickets to friends whom they think proper to have admitted to the gardens [cheers]. He felt certain that unless the Society gave greater facilities and privileges to members they could not by any means raise their income to £10,000 a year. Of course the Society could increase their receipts by diminishing their expenditure [a laugh]. But then the question was, Did any means exist by which the expenditure could be reduced? [hear, hear]. The cost of the gardens had gone on increasing, and it should be borne in mind that the cost of their maintenance was not taken into account [hear, hear]. Indeed, as most of the Fellows knew, it was not taken into account at all. And after all it was the great cost resulting from the management of the gardens which had affected and brought the Society into its present position [cheers, and a cry of "no"]. At any rate, his lordship believed that the true interests of horticulture would be promoted by the severance of the horticultural element from South Kensington gardens ["no" and "yes"]. He could not and he would not believe in these gardens being converted into bricks and mortar for the benefit and at the will of the Commissioners [loud cheers]. With regard to the Horticultural Society he believed if they only went back to their old quarters at Chiswick—he should indeed say their original quarters at Chiswick—would certainly bring about a better state of feeling amongst horticulturists, and a bright future for the Society. There was really a noble love for horticulture in the people of this country. People saw that in the number of growing societies, but these had no cohesion in them, or rather among each other. Well, one thing he should suggest was that a system of lecturing on the principles and the science of horticulture should be adopted [hear, hear]. The Society ought, by means of correspondence, have itself in communication with the horticultural societies of the Continent. Indeed, even from America and Australia the Society ought to be able to have, if its correspondence were properly carried on, a large amount—indeed, a very large and important amount, of continental and American news. He should just like to remark that he should think it was advisable to come to some decision as to the alteration of the Charter. He should not at the present time trouble them with any

schemes of his own, but, he might sincerely say—and he knew all the Fellows present believed him—that he had the real interests of the Society at heart. He thought, and he said it with great respect for the Council, that if they took back their proposals and reconsidered them, he doubted not an agreeable method for solving their difficulty and saving the Society would be amicably arrived at [cheers]. If the propositions of the Council were adopted the Charter would have to be altered, and at the same time horticulture would have to be practically abandoned ["hear, hear," and cries of "no, no"]. Lord Alfred Churchill concluded in the following words: I think it the Council would take back their proposals and reconsider them, I doubt not that we shall come to the adoption of a more agreeable method likely to benefit the Society [applause].

Mr. LIGGINS said he disagreed *in toto* with the propositions of the Council, which he thought would do the Society more damage than probably they ever expected to receive [a laugh]. He had never heard a statement which more surprised him than that of Admiral Hornby made at the last meeting. And for this reason that he (Mr. Liggins) being a resident of Kensington for fifty years claimed to know the feeling of Kensington, and he was therefore quite surprised to hear Admiral Hornby's opinion—that was the opinion of a perfectly new member leading them into a fog [laughter]. It was stated by the Admiral that the most disastrous results would occur, not to the Council alone, but to the whole body of the Fellows.

THE PRESIDENT.—Was that a statement made at the present meeting?

Mr. LIGGINS.—No, it was a statement made at a former meeting.

THE PRESIDENT.—Oh, then, it was not on the present occasion, so please don't refer to it [hear, hear].

Mr. LIGGINS.—Well, I will shorten my remarks, and I say I am not going to be shunted out of the Royal Horticultural Society [much laughter]. I claim the right to my own privileges [loud cries of "hear"]. As an old four-guinea Fellow I do not think the Council have any right to touch my privileges [loud cheers]. I have always enjoyed a transferable ticket. Well, are my wife and my daughter not to use it? [cheers and counter cheers]. I think a gentleman says "No." Well, if not it would be a perfect waste of money to throw it away upon subscriptions to the Royal Horticultural Society [hear, hear]. From conversations I have had with many Fellows of the Society I find that a general feeling prevails that they, as a body, are determined not to give up their privilege of being possessed of transferable tickets [cheers]. I hope I express the feeling of the meeting [cheers and dissent]. We are all anxious to raise the income of the Society.

THE PRESIDENT.—How? [loud cheers and laughter].

Mr. LIGGINS.—It is not for me to dictate to the Council ["oh," laughter, and cheers]. Mr. Liggins went on to say that he thought there would be no difficulty in the Council raising the income of the Society; but if the Council wanted to increase the revenue of the Society it must be done by means of increased facilities at reduced cost. It was a perfectly backward movement to take away the privileges of the Fellows; and more than that, he felt perfectly certain the Fellows would not submit to it [cheers and laughter]. He hoped the Fellows would not stand upon the subject of the resources of the Society, but would stand as men, and continue to be Fellows of this fine old Society [cheers]. Speaking of the question of transferable tickets Mr. Liggins said it was not a very pleasant thing to be told that Fellows had been mis-using tickets, and were dishonourably doing so.

THE PRESIDENT.—Nothing was said about dishonour.

Mr. LIGGINS.—The word "dishonour" may not have been used, but the language of the noble Chairman was rather harsh.

THE PRESIDENT.—I must say I do consider it an abuse when the members of another household are enabled to visit the gardens by the use of the name, or rather the ticket of a Fellow of the Society [loud and prolonged cheers].

Mr. LIGGINS.—That is quite my view [cheers and laughter].

THE PRESIDENT.—Now, that abuse exists very largely. It does not exist as far as I am personally concerned, although I am a four-guinea Fellow, but I think it is really discreditable to those who practise that abuse [cheers].

Mr. LIGGINS.—It is utterly hopeless, or at any rate something like probable, for us to raise in the four or five years our income to £10,000 without giving greater facilities to the Fellows. If we could get a skating rink constructed, there is a fine piece of ground which is not wanted at all at the corner of the gardens.

THE PRESIDENT then in answer to Lord Bury, said that it had been submitted to him by members of the Council, that to their own knowledge the practice of transferring tickets existed, and he assured his friend that he (the President) was not taking any personal interest in the matter.

After a short discussion in which Lord Bury distinctly challenged any person to show, or give any proof, how the power of transferring tickets was abused,

Admiral Hornby (Council) said—Now the noble lord com-

plaints of the statement made. I will say that these tickets have been transferred from end to end, not of the West End, but of London [cheers]. What is the case? It is this, that people from all ends and sides of London get tickets, probably from the servants of Kensington and Brompton [hear hear]. Now, without entering into this matter more fully than perhaps would be pleasant to those concerned, he could honestly say that no less than five families had been in the habit of using his very own tickets.

A FELLOW.—Who is to blame? [cheers].

Admiral HORNBY.—Nobody, I submit, is to blame. You may not know it—probably you do not—but I can tell you positively that it is a constant arrangement that these tickets pass from one end to the other end of a fashionable neighbourhood. The fashionable people are not ashamed to use them, and they do use them. Now, there are plenty in this room who know I am speaking the common perfect truth, when I declare that many ladies and gentlemen living in the west end of London use the gardens of the Royal Horticultural Society without contributing one farthing towards their maintenance. I have no personal interest in this matter, but I have come upon this Council at the request of the people of South Kensington, because they thought I might do good, and because they knew I wished well to the Society [cheers]. I do say distinctly that these transferable tickets are abused [hear and cheers, and cries of "no"]. Very well, some one says "no." Well, I believe if the transferable power were taken away the Society would be saved [loud cheers].

A long and uninteresting discussion, in which Mr. Bowen and Mr. Shepherd took part, which was chiefly in favour of a skating rink, took place, and then the practical part of the business of the meeting was resumed. Sir Alfred Slade, Bart., said he thought it right to ask the opinion of the meeting on the propositions of the Council, but neither the honourable baronet nor the noble lord (Bury), who was of his party, waited for the conclusion of the proceedings. But this was the case, notwithstanding Sir Alfred Slade before he left the room making use of the following words:—"I do think it right to ask the opinion of this meeting on the proposals of the Council." The baronet generally took objection to the schemes of the Council, and then Mr. Bateman spoke of the necessity of the Society looking at the "extreme gravity" in which it was placed. In conclusion of a lengthened speech which dealt with the general details of the Society, Mr. Bateman said he should move, "That this meeting be adjourned to give a sufficient and proper time to the Council to reconsider their propositions" [loud cheers].

Mr. STEWARD seconded the motion.

Mr. W. H. JACOB asked the meeting not to adopt the suggestions of the Council, although he might say his tickets were no use to himself or family. Indeed he had sent his tickets to those who had children, that the latter might be sent to the gardens. That he did not think was what the noble Chairman called an "abuse" [cheers]. In conclusion he begged to move, "That this meeting begs to ask the Council of the Royal Horticultural Society to reconsider their suggestions to the Fellows" [cheers].

Mr. CHARLES MORGAN seconded this motion or amendment, and remarked that it was a shame the scheme of the Council did not provide for families.

The PRESIDENT.—The resolution to which you have moved an amendment does provide for families. I mean the new regulations proposed by the Council, which may be taken in the form of a resolution.

Mr. LITTLE (member of Council) in a few well-chosen words spoke of the absolute necessity of those who used the gardens paying for them, and he added that if they took the population of the noble houses around the gardens they would find that not more than 10 per cent. were Fellows of the Royal Horticultural Society [cries of "shame"]. But then there were great numbers who used the gardens but never paid for them. Probably after the publication of the proceedings of this meeting those ladies and gentlemen who had been enjoying the gardens a long time at no expense might see the necessity of contributing something towards their maintenance [cheers].

Mr. KNILL said he should neither vote for the resolution nor the amendment.

Mr. SHEPHERD hoped that like himself there were Fellows willing to give up some of their privileges for the common benefit of the Society.

A FELLOW.—I am afraid not.

Mr. SHEPHERD.—I should be sorry to think that selfishness was a characteristic of the Fellows of the Royal Horticultural Society [cheers, and some laughter].

Mr. CAIRD recommended that the Council should reconsider their scheme.

After some conversational discussion

Dr. PINCHES moved "That the Council be requested to reconsider the privileges for 1876."

Mr. LISGINS seconded the amendment, which, of course, was substantially a negative to the propositions of the Council.

Mr. W. HAUGHTON (Council) wished to say he was the sole dissident with the majority of the Council on the question of transferable tickets.

After a short discussion the amendment proposed by Dr. Pinches (which was afterwards put as a substantive motion in consequence of the proposal of a number of motions and amendments to the same effect) was unanimously agreed to amid some cheering.

LORD CARDWELL rose and said:—My Lord Aberdare, whatever the conclusions at which we ultimately arrive may be, we know that without harmony and support of authority we shall not be able to get out of the difficulties of our financial position [cheers]. I think we are extremely fortunate in having you, my Lord Aberdare, at the head of our proceedings [cheers]. We have taken into consideration at great length a great number of proposals, and that has led to the conclusion, which I understand we have given, that the Council will reconsider and resubmit them. Like many others I am one of those who took a forty-guinea ticket, and I may say I think we ought in this matter make considerable concessions, because it has been clearly shown that while these local admissions are in existence it tells upon the accession of new subscribers; and I think I need not tell you that without a large accession of new subscribers we cannot get on. I am glad, my Lord Aberdare, that you and the Council have accepted the motion; and I hope, as I have no doubt you will, reconsider the proposals in the interval between this and the next meeting, and that you will be able to bring forward proposals which the Fellows will be ready to accept. I beg to ask of you, ladies and gentlemen, to give your cordial thanks to the noble Chairman for his conduct in presiding at this meeting to-day.

The motion was carried with acclamation, and Lord Aberdare having replied briefly, the protracted proceedings were brought to a close.

## NOTES AND GLEANINGS.

In reading Dr. LIVINGSTONE'S "LAST JOURNALS" we have many times had regret forced upon us that he had no botanical knowledge, nor any supplies to aid the natives of interior Africa in their gardening. Continually occur notices of trees and plants without any information enabling us either to identify them or to determine the natural orders to which they belong. The chiefs, as well as all the people, delight in cultivating the soil, and the cultivation is judicious. They trench the soil, burn the weeds slowly by covering the heaps with sods, and they spread the ashes over the surface; they irrigate their crops until the rainy season arrives. Peas, Beans, Pumpkins, and other crops are mentioned, besides many fruit trees. Of these last is the Fig tree. It is, says Dr. Livingstone, "always planted at villages. It is a sacred tree all over Africa and India, and the tender roots which drop down towards the ground are used as medicine—a universal medicine. Can it be a tradition of its being like the Tree of Life, which Archbishop Whately conjectures may have been used in Paradise to render man immortal?" In future African exploring expeditions we hope a botanist and a gardener will be of the party, and a good store of useful seeds be with them.

— We have received the schedule of the GREAT EXHIBITION OF HORTICULTURAL PRODUCTS which is to be held at Brussels on the 30th of April, 1876, in celebration of the hundredth anniversary of the Société de Flore de Brussels. It is an unusually rich one, and besides collections of plants and groups it has special classes for no less than 104 distinct genera. Besides the prizes of the schedule there are four special prizes of honour. To the foreign exhibitor who, by the richness and merit of his collections, shall have contributed most to the splendour of the Exhibition—first prize, a large gold medal offered by the King; second prize, a gold medal offered by the Comte de Flandre. To the Belgian exhibitor who, by the richness and merit of his collections, shall have contributed most to the splendour of the Exhibition—first prize, a large gold medal offered by the Queen; and second prize, a gold medal offered by the Comtesse de Flandre.

— THE YORK SOCIETY OF ANCIENT FLORISTS held its annual meeting on the 7th inst., when arrangements were made for the shows of the coming year. On the 9th the members held their annual feast convened by a summons on which the Royal arms have not the white horse of Hanover, which indicates that its foundation was before the Georges.

— ON the 6th inst. Mr. MECHI took a final leave of THE FARMERS' CLUB. After delivering a very sound lecture on "The Treasures of the Air, the Soil, and the Subsoil," he concluded by observing that having attained his seventy-fourth year he considered his agricultural efforts concluded.

No man has effected more cultural improvement by the combination of sound science and practice than Mr. Meehl, and no one can point to existing evidence with more certainty than ourselves, for we know what his Tiptree land yields now, and we knew personally its comparative sterility when he entered upon its cultivation.

—We regret to hear that the *PHYLOXERA* has made its appearance in the vineyards of Tarragona and also in different parts of Portugal. The Spanish Agricultural Council were to meet Dec. 11th, to consider the best means of arresting the progress of this scourge.

### A PROLIFEROUS POINSETTIA.

SINCE the introduction of the well known plant *Poinsettia pulcherrima* from Mexico forty years ago it has been without a rival as a distinct, scarlet-bracted, winter-decorative plant. It is now, however, likely to be effectually superseded by a new and totally distinct form, which has also been discovered in Mexico by M. Roehl, and which is regarded by that collector as the most valuable of all his discoveries. The entire stock of the new *Poinsettia* is in the possession of the Messrs. Veitch, and is now in full beauty at their nurseries at Chelsea.

The examples which we have seen of this plant are remarkable alike for the size of the heads, their form, the distinct character of the bracts, and their marvellous brilliancy of colour. In the old type the plant is surmounted by a single cluster of yellow flowers, from the base of which the bracts radiate in a horizontal manner. In the new form the central or primary cyme, which is surrounded by splendid bracts, is, as it were, the root of other flowers which spring from it on short simple stems, each surmounted by flowers and bracts; and these secondary heads become further subdivided, and forming also perfect flowers and bracts—the head, in fact, culminating in a multiplication of parts, each perfect and of extraordinary brilliancy. The individual bracts differ also from the normal species by their longer petioles, so that each principal bract, instead of extending horizontally, is gracefully arched after the manner of the leaves of *Dracæna Cooperi*: thus each head forms a perfect cone of colour, and not a simple flat disc as in the old species.

The head which we more particularly noted was 16 inches in diameter, and from the base to the apex of the cone of drooping bracts was 11 inches in depth. The bracts on this head were fifty in number, arranged on seven separate cymes which had sprung from the primary base. The colour is superlatively brilliant, as if a delicate tint of orange floated over the intense scarlet, imparting a more dazzling appearance than is possessed by the old species. If the designation "a cone of fire" is applicable to any plant in existence this is the one; and if it proves constant to its character, as every head we have seen is constant, it is a plant which must find its way into all gardens in all lands where stove plants are cultivated, and form a brilliant monument to the researches of Mr. Roehl.

### FRUIT KEEPING AND ROOM.

FROM what I have read and heard from various parts of the country Pears and Apples are keeping very badly this year, which is attributed to so much wet during the end of the autumn. Both Pears and Apples are keeping as sound with me as they generally do at this season of the year. Louise Bonne of Jersey, Comte de Lamy, Marie Louise, Durondeau, Haeon's Incomparable, Aston Town, and Winter Nells are all as sound as when gathered. Some of them are unusually large. Kerwick and Manks Codlins and Lord Suffield Apples were only finished on the 20th of last month. Celini, Round Winter Nonpareil, Beauty of Kent, King of the Pippins, Ribstone, and Golden Noble we are using at present.

My fruit room stands almost due south and north, apart from any other building except a small room at one end used for storing away early and late seed Potatoes. It is ventilated at the top, both ends and sliding shutters, also two trap-doors in the roof of the ceiling, which causes a regular circulation of air during the storing-away season, and dries up the overabundance of moisture given off when the fruit is first gathered. There is also a sliding ventilator in the top of the door, and the inside of the window closed up with shutters which meet in the centre right and left, so that they can be opened with very little trouble when required, as they slide in

a groove into the hollow walls so that no frost can enter; when the weather is unusually severe we can put on a fire, but is seldom used. There are six tiers of shelves 2 feet wide, with strips of wood 2 inches wide and 1 inch apart between, so that the air circulates right under the fruit.

How often do we see fruit rooms put up on the back wall of hothouses, which is too hot and dry for keeping fruit any length of time, as it ripens too prematurely and shrivels. I sent in on Midsummer-day a dish of Sturmer Pippin, Braddick's, and Old Nonpareil, as sound and fresh as when gathered, fine in colour and flavour, when I have seen the same varieties shrivelled up by the end of April in fruit rooms put up at the back walls of hothouses.—WILLIAM MACPHERSON, *Snelston Gardens*.

### PHLOXES.

THEY can be grown from 1 foot to 18 inches in height by striking the young shoots late in spring. When rooted report them singly in small pots, ready to be planted out into beds or borders where they are to flower. During the summer they will throw up heads of their richly-coloured flowers, of which there is a great variety. We generally find them stuck among shrubs in some out-of-the-way corner of the garden struggling for life, but all lovers of flowers ought to allot a prominent place for these fine herbaceous flowering plants. They are especially well adapted for pot culture, for decorating the greenhouse or conservatory, and when well grown they will surpass many of the usual greenhouse flowering plants. They are easy to manage.

I now name a few sorts worthy of note, as follows:—White Lady, Mons. Guldenschuch, Edith, Deliverance, Mrs. Dombrain, A. Verschaffelt, Mons. Domage, Madame Moisset, Madame la Comtesse de Turenne, Chanzy, William Rollison, M. Gustave Doré, Mons. Lannay, Etoile Merully, Madame Antin, Flora Macnab, Mars, Daux, Mons. Hughson, L'Avenir, Rex, Madame Atzer, Lohair, Haroules, Miss Robertson, Socrates, Mrs. Greenshields, Chatiment, Coquette de Parc, Rosa Alba, Baron de Charette, Rêve d'Or, Cocineas, Prima Donna.—E. H., *Mountains, Hildenborough*.

### ROLLESTON HALL.—No. 1.

THE SEAT OF SIR TONMAN MOSLEY, BART.

THE estate of Rolleston has been in the possession of a long line of owners of high and ancient lineage. It is directly traceable to the ownership of Edward the Confessor, and was subsequently enjoyed in turn by Earl Toeti, Morear Earl of Northumberland, Robert de Ferrers (first Earl of Derby), Sir Henry de Rolleston (whose descendants resided here for four centuries), the estates eventually passing by purchase into the Mosley family in 1614.

This family is also of ancient lineage. Near Wolverhampton is the hamlet of Moseley, derived from the Saxon Meos (Moss) and Leay (field); in Domesday it is called Moleslel. Of this hamlet Ernald became first tenant and then owner, and, as was the custom in those times, derived his surname from the place of his residence—thus Ernald de Moseley. Ernald's sons, Oswald and Osbert, migrated to York and Lancaster, and gained a substantial position in the latter county, Nicholas Moseley, Esq., becoming established on an estate at Hough End near Manchester. In 1596 this gentleman purchased the rights and appurtenances of the manor of Manchester, which continued a part of the hereditary possessions for 250 years; these rights, after much litigation in their defence, were sold to the Corporation of Manchester in 1846. In the collegiate church of that city memorial plates are inscribed to Sir Oswald Mosley, lord of the manor of Manchester.

Nicholas Mosley was Lord Mayor of London in 1599, and was knighted by Queen Elizabeth to mark her high approbation of his services during that period, Her Majesty at the same time presenting him with a richly-carved oak bedstead and other furniture. The bedstead was unfortunately destroyed in the disastrous fire which occurred at Rolleston in 1871, some of the other furniture being preserved, and is now as bright and sound as when it left the carver's hands. In 1720 Oswald Mosley was raised to the baronetage by George I. Sir Oswald was succeeded by the Rev. Sir John Mosley, who restored the mansion in 1757. Sir John was a gentleman of benevolent disposition but eccentric habits, as may be gathered from the following characteristic address which he delivered at a meeting of noblemen and gentlemen at Stafford, who had assembled

for a charitable purpose and had put down their names for various sums. Sir John, who was attired in a threadbare coat and was unknown, rose from his seat and said, "I have ridden four and twenty miles on one horse to attend this meeting with £50 in my pocket, with the intention of giving it in this good cause; but when I see upon the subscription list which has been handed round the names of noble lords and wealthy gentlemen with such paltry sums attached to them, I fear I should be shocking their feelings were I to carry my intentions into effect; and am therefore constrained to replace in my pocket the greater part of it, which I shall reserve until some future occasion, when a spirit of liberality may be more prevalent among them." All eyes were directed to the speaker, and before the general inquiry of "Who is he?" could be answered, he was again on his horse and off to Rolleston.

In due course the late baronet, Sir Oswald Mosley, D.C.L.,

etc., succeeded to the estates; he was a gentleman of great literary attainments, and was an accomplished botanist and naturalist. His history of the fauna and flora of Staffordshire betokens great knowledge and research, and the botanical garden which he established at Rolleston was unusually extensive and complete. He also wrote the family memoirs, and a few lines from its admirable preface will testify to the high character of the author. Sir Oswald says to his children that he "writes not to fill their minds with arrogant notions of high descent, but with the humble hope that by recording the virtues and failings of their ancestors they may imitate the one and avoid the other, and under all circumstances trusts that they will take, as the only one test and guide, the word of God."

Sir Oswald died in 1871, and was succeeded by the present baronet, Sir Thomas Mosley, a true specimen of the English

Fig. 112.—ROLLESTON HALL—CONSERVATORY AND GROUNDS.

gentleman, and under no previous owner have the mansion, grounds, and gardens at Rolleston had greater and more tasteful additions made to them.

**THE MANSION.**—Immediately on his accession to the baronetage the present owner commenced making great additions to the mansion, but the fire, before alluded to, occurring in the same year, was so extensive as to necessitate the erection of an entirely new structure. This was completed in 1874, on the site of the old hall. The structure is square and commodious, being built of stone, and ornamented with stone balustrades. It occupies just an acre of ground, and is fitted with every modern convenience, including an hydraulic lift. The rooms are spacious and richly furnished, and contain pictures by eminent ancient and modern artists, including a fine presentation portrait by the tenantry of Sir Oswald Mosley. The library is extensive and choice. The oak staircase is very elaborate. In the drawing-room are splendid cabinets and vases which were removed from France during the Revolution, and which had been the property of Louis Philippe. The front hall is decorated with ancient oak furniture, armour, pedestals, vases, bronzes, and civil paraphernalia. Adjoining the mansion is the

**CONSERVATORY.**—This is a very fine structure with a central circular roof, and ridge-and-furrow side roofs, supported by light iron columns. It communicates with the mansion by

large glass doors, one entering the ball room, another the corridor, with access also to one of the side rooms. Thus one side and end of the building is in connection with the mansion, the other side and end facing the grounds and receiving light. The building is 70 feet in length by 50 in width, and about 40 in height. Gas globes are suspended from the roof, and the structure is lighted on special occasions, open tubes ascending from the globes, through the roof, which prevents the slightest injury ensuing to the plants. In the centre of the building is a handsome white marble fountain set in a basin of the same material, in which gold fish will be placed. There are broad central and cross paths with a path round the building, but 2 to 3 feet from the sides and ends; that space on the light side is occupied by a flat stage covered with gravel for pot plants, and on the wall side by a border for trained and climbing plants. The body of the building is occupied by four beds, the two on the dark side having as central occupants a splendid pair of *Dicksonias*, the others being planted with *Cissampelos*. At the corners are nice plants of variegated *Yuccas*, and on each side the ball-room door are a fine pair of green *Dracaenas* matched by a smaller pair of *Araucaria excelsa* at the opposite or garden entrance. The roof and columns are being draped with climbers—*Pasiflora*, *Clematis*, *Lapageria*, red and white; *Taxonia Van-Volxemi*, *Bougainvillea*, *Acacia*, *Habrothamnus*, *Abutilons*, and *Rhynchospermum*. The above are the permanent

plants. Associated with them were Poinsettias, of which hundreds are grown having discs of 10 to 14 inches in diameter; Solanums and Chrysanthemums, very large and fine; Richardias, winter-flowering Pelargoniums with trusses as fine and fresh as at midsummer, Harold, Excellent, and Vesuvius being the best; and several large plants of Sericographis Ghiesbreghtiana—this useful old plant is grown after the manner of show Pelargoniums, and in winter its glossy foliage and scarlet sprays are invaluable for cutting for indoor decoration. These are a few of the plants which were in bloom in October, and a more brilliant display can seldom be seen at any period of the year. Basket plants are also suspended from the roof, the most effective being *Aspidistra lurida* variegata fringed with *Tradescantia zebrina*; *Adiantum cuneatum* fringed with *Mesembryanthemum cordifolium variegatum*; *Adiantums* fringed with *Saxifraga sarmentosa*, and *Platycoerium* and green and variegated Ivy-leaved Pelargoniums. Besides the plants are birds which warble their songs of spring in the genial temperature which is provided, and these with the flowers, roomy premises, and inviting chairs which are provided, make the structure in the highest degree enjoyable. Externally it is appropriately ornamented, and is in excellent keeping with the surrounding architecture. It was erected by Mr. Ormson of London, and it is admirably furnished by Mr. Buck. Passing from its portals we enter

THE GROUNDS.—These are extensive, embracing upwards of fifty acres. The late baronet took great delight in the surroundings of his mansion and added much to their attractiveness, but he did not decorate in the "gorgeous style" and set his garden aglow with scarlet and yellow; he was too much of a botanist for that, and loved trees, and flowers, and Ferns for their own inherent beauties, and not because they would "go well" with any particular system of embellishment. He therefore planted trees, but not in formal lines; dells and hollows he transformed into caverns and grottoes for his Ferns; made rustic buildings, and arranged his plants in systematic and botanical order. This work still remains and speaks highly for his taste and industry. The present baronet has also improved largely—in fact he is continually improving—improving yet preserving. New lawns have been made, and Conifers permitted to develop themselves; drives and walks have been judiciously formed, and structures erected both of an ornamental and useful character. The site is generally flat, the mansion overlooking a park of considerable extent containing fine trees and effective water scenery. The lawns contiguous to the mansion are very spacious, and contain isolated specimens of deciduous trees and some very fine Conifers. Near the mansion is a terrace walk about 100 yards in length ornamented with vases, and in the summer with several fine specimens of *Aloes*. Near the extremity of the terrace in a square recess fronting Sir Tonman's private apartments is a flower garden, the design being appropriate to the architecture; and this in summer is furnished with bedding plants, in winter with hardy plants, and in spring is gay with bulbs. From the terrace are many pleasing views, one of which, showing the church in the distance—a venerable structure about to be restored, is shown by our woodcut. In this view glimpses are obtained of some of the Conifers, the finest being a specimen of *Abies Douglasii*, the branches sweeping the lawn and measuring 52 yards in circumference. This specimen having lost its head a few years ago, Mr. Buck, with the aid of ropes and the assistance of an adjoining tree, fastened upright one of the side branches, which has formed a perfect substitute for the original leader. Another Douglas Fir raised from a cutting by the late baronet is now 80 feet high. There are also several good *Wellingtonias* and many fine Cedars of Lebanon. *Cedrus atlantica* is also in excellent condition, as are *Piceas pinus*, *Nordmanniana*, and other popular sorts. The lawns also contain very fine Yews, which have been judiciously tended; also Hollies and other shrubs, including *Rhododendrons*, flourish admirably in the strong clayey soil. The pleasure grounds extend to the reservoir, which is nearly a mile from the mansion, and is approached by an avenue of choice young Conifers. The reservoir was made by Mr. Buck to supply the mansion and gardens with water, and it must be admitted that he has accomplished his task in a highly successful manner, for no adjunct to the residence is more useful than this, and none more ornamental.

Another attraction of Rolleston is the hardy fernery. This is formed in a hollow, and is approached by walks curving through the shrubbery. It is completely embowered in foliage, and is an enjoyable retreat during the sultry days of summer.

The natural formation of the ground has been taken advantage of, the hollows having been deepened and the hills raised. These have been faced with rocks, and are charming by their very ruggedness, and the tortuous passages leading under arches into capacious caverns are richly clothed with Ferns. One of these grottoes is 50 yards in length, and is capable of affording accommodation to a large festive party, to which purpose it has been frequently devoted. How many natural hollows are there in shrubberies which are occupied with rubbish, which by a little, and only a little, tasteful application of art may be transformed into ferneries, and which as summer retreats and attractive nooks would contribute immensely to the diversity and interest of a garden? There are many such places, and the rocky dells at Rolleston are an example of how they may be beautified, and how appropriate they are for the cultivation of this elegant family of plants. In this dell the *Osmundas regalis*, *cinnamomea* and *cristata*, *Struthiopteris germanica*, *Lastreas* in variety, and *Oncoclea sensibilis* flourish luxuriantly; while equally healthy but of more lowly growth are *Aspleniums Ruta-muraria* and *marinum*, *Adiantum pedatum*, *Trichomanes radicans*, with thousands of the Hart's-tongue, Beech and Oak Ferns, which in cool spots and the shade which trees afford, will flourish in almost any sort of soil.

A notice of the more useful department of the gardens at Rolleston must be postponed; but here also considerable improvements and additions have been ably carried out by Sir Tonman's old servant and skilful gardener, Mr. Buck.—J. W.

### ATRIplex HALIMUS AS A SEASIDE PLANT.

Of late many inquiries seem to have been made about plants suitable for the seaside, and lists have been given; but there is one shrub which I noticed a few months ago at a fashionable seaside place that I do not recollect having met with before, neither is its name mentioned in any nurseryman's catalogue of shrubs. It was flourishing remarkably, and I expect will do so also in other places of a like kind. It is an old plant—at least it is reported to have been introduced into this country as long ago as 1640.

*Atriplex Halimus* is an evergreen shrub with foliage of a glaucous hue, habit bushy, and very distinct from other seashore shrubs. I believe it to be closely related to the garden Orach, and there is said to be one or two British species also of an eatable kind belonging to the genus. The species mentioned above seemed to make a neat and convenient hedge, to which purpose it was often put in front of some of the villas at Bournemouth, and its appearance indicated that it grew as fast as was wanted. It did not seem to object at all to any kind of soil offered it. The natural soil of the place is sandy or sandy peat; but we all know that in the immediate vicinity of a house newly built the material dug out of the cellars, &c., is mixed with the top soil, and in the place I speak of there were beds of a reddish kind of clay met with now and then not by any means inviting to vegetation, yet I think this plant did not object to it.

I believe it to hail from Spain, and though it has been in this country more than two centuries it is far from being well known, but it certainly deserves a trial in places where there is a desire to vary the ordinary list so often met with; and although there are many shrubs more to be admired than it is, the number that will bear the spray from a regular south-wester is only limited. Planted, therefore, along with Broom, Tamarisk, Gorse, Heath, and other plants, the chances are that this one will maintain its place. "And what is this?" is an inquiry the planter will probably often have made him; and possibly on that account he will think none the less of it. Of its hardihood for inland purposes I know nothing, but expect it is not without its faults, or it would have made its way long before this into general planting; but if it will do in very exposed places on the seashore it is well worth patronising, and I suppose by its appearance that it is not difficult to propagate.—J. BOBSON.

### APHIDES IN WINTER.

Most horticulturists must have noticed these insects in winter at full play (or work) in greenhouses that contain Geraniums, where the plants have not been properly attended to in the autumn, so that a juvenile brood, brought under cover while of small size, under a fostering warmth becomes fat and flourishing. I find, however, that aphides in small

numbers may be found on various plants out of doors during the dull season of the year. Nor have they been affected, seemingly, by keen east winds at the end of November—in fact, some gardeners, holding by the old theory that there are blight-bringing winds, believe that this blight in particular migrates thus at all seasons. Conclusive against this, however, is the wingless state of the aphides now about. Though in the bulk of the species belonging to the genus *Aphis* the egg state carries on the succession from autumn to spring, Nature probably does also protect from a possible extinction some of the species by keeping alive a few individuals as imagos during that period.—J. R. S. C.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

**CUCUMBERS.**—Early Cucumbers are held in high estimation by almost everyone, and their production is often an object of a little wholesome rivalry as to who can out the first fruits fit for the table. Cucumbers are forced in structures heated by hot water, and also in common garden frames by dung heat. The latter may be designated the old-fashioned plan; nevertheless it is practised by many, myself among the number, and I am sure that the amateur will find that Cucumbers can be advantageously cultivated in that way, although more attention may be required than is the case when more modern structures heated by hot water are provided. I do not with frame culture advise that the plants be raised until after the shortest day, or they would remain long in a weakly state before having the advantage of bright weather.

As dung beds are so useful in a garden I advise that, if they are provided and sufficient heating material can be obtained, two frames should be set up—that is, a one-light first for raising the plants, and which can afterwards be used for raising other seedlings that may be necessary, and a two-light frame for fruiting the plants.

To those who require early Cucumbers I would say, Now is the time to commence operations by collecting daily as much fresh horse dung as possible, and place it in a heap under cover if convenient, and on a dry bottom (but this is not absolutely necessary), and mix quite one-third of fresh-collected leaves with it, which will help to sweeten the whole and save the manure. This heap must be turned at intervals of three or four days and be mixed thoroughly; and if there should be any indications of its heating itself dry a little water must be applied at the time of turning. When the whole has become sweet make up the bed.

Select a dry bottom for this, and with as much shelter on the north and east sides as can be obtained, and at the same time in a spot where the most sun can be secured. Do not lay the dung on the bare ground, but let the allotted space be first covered with a thin layer of wood or a layer of rough litter, just to keep the cold ground from acting upon the hot dung. Make the bed about 4 feet 6 inches high at the back and 3 feet 6 inches in front. This will sink quite 6 inches, but it will be large enough to afford the requisite heat, and the frame will have a good elevation. Make the bed 6 inches or more wider than the frame on all sides. In making it up take care that it is evenly done—that is, all must be made firm alike, or the bed will sink on one side more than another; and again, if the manure is not properly mixed one part will heat more violently than another and so endanger the plants. Put the frame on at once and leave the lights a little open at the top to let out the rising steam. When the violent heat has subsided, which can be proved by a trial stick inserted in the centre of the bed, it will be safe to put in the soil.

**Soil.**—This varies with many cultivators. Some use one mixture and some another, but in my experience it matters little about any particular fancy mixture. The Cucumber likes a good staple soil which must consist of loam which has been laid up for some time, and mix with it some well-rotted leaf mould, or, in the absence of that, rotten dung that has been reduced by decomposition to almost a black mould: both of these ought to be dry or nearly so. Place the soil in a heap in the upper part of the frame—about two barrowful will be sufficient—and after this has become warmed through the seeds may be sown either in the soil or in a pot of the warm soil and gently watered. The young plants will soon appear, and when large enough they should be potted off in the same sort of soil that is in the frame. Of course while this is going on the material for the other bed should be prepared and be made ready for the reception of the plants when large enough, but if no other frame is needed then put a plant or two out in the soil already in the early frame, water with warm water, and shade for a few days if the sun comes out.

**TEMPERATURE AND VENTILATION.**—The heat should be 75° or from that to 80°, but the temperature ought not to be below 70° at night; in the daytime the sun-heat will make a difference but a few degrees increase, though that will be an advantage. While steam rises half an inch of air may be left on all day and about half that during the night, taking care that the opening is

covered by a mat to stay the ingress of cold winds. As the plants grow and increase in strength, and the season advances with more light and sun, the system of airing, watering, and closing must be altered accordingly. Take care also to always have plenty of material ready for lining the bed when the heat is found to be declining. To do this some care is also necessary, for if done all round the frame at one time the chances are that the heat would be too much increased, therefore do either the two sides or the two ends at one time. Always protect the bed by straw mats or loose straw, for if severe weather sets in this will prevent it from taking so much effect. Of course the lights must be covered regularly every night; the glass, too, should always be kept clean, which affords the plants more light and consequently they gain strength.

**Sorts.**—These are very numerous. The true Telegraph is a thoroughly good frame as well as house Cucumber, and an excellent cropper, yet it is not so strong in constitution as some others. Cooling's Derbyshire Hero is a capital frame Cucumber, but even this when grown by the side of the old Syon House or Lord Kenyon's Favourite is not nearly so early. At one time I always grew the latter sort, but have not had it true lately. It is a short, smooth-skinned sort; it has a firm flesh of good flavour. This or any of the other sorts I have named above are well worthy of cultivation.—THOMAS REED.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

##### KITCHEN GARDEN.

The ground is still thickly covered with snow, which is very gradually melting by day, so that it is not possible to do anything on the ground. Two common sources of annoyance in gardens are rabbits and mice. Where the kitchen garden is walled-in the first-named are easily kept out. In our case a large portion of the boundary is protected only by galvanised wire netting; through or under this material they frequently find or make a passage, and do much damage to kitchen-garden crops, also barking young fruit trees. We have trapped them by scratching a hole in the way the rabbits do it themselves, and placing a trap on the top. A much more preferable way is to hunt them out of their shelter and shoot them. Mice are also very troublesome; they destroy bulbous roots, especially Crocuses. Peas in drills are also sure to be attacked. Radish seeds sown under glass invariably attract them, being preferred to those of Lettuce, although they will scratch up and eat the latter greedily if no Radishes are sown under the same lights. Traps of different constructions are used to destroy them. The figure-of-4 trap is easily set with a brick which falls on the mouse, instantly crushing it. Another very simple and effective trap is formed by placing two pieces of wood in the ground about 5 inches apart. A thread on to which three Peas have been strung and fastened at each end to the sticks supports a brick; the mice in gnawing the Peas out through the thread, which causes the brick to fall down upon them. Many different varieties of traps may be bought at any ironmonger's. All the forms of wire traps must be protected from rain, else the wires rust and do not spring readily.

There is always plenty of work to be done in bad weather; we are now cutting out pegs, sticks, and supports for Strawberries, both out of doors and in the house. The smaller branches from Elm, Beech or Hornbeam are the best materials from which to make them. For out-of-door Strawberries we use small branchlets about a foot long, with all the spray left on; these are just stuck into the ground close to the plants after the fruit is set. The fruit hangs over the axils of the sprays. Those used for pot plants are trimmed-in closer, three or four forks only being left at the end: it is necessary to study neatness when it can be done without being antagonistic to utility. When the weather is frosty advantage of this will be taken to wheel manure on ground intended to be trenched or dug. One often sees manure laid on the ground in barrowloads; this may be convenient, but it is the worst thing that can be done with it. Spreading it out would be better, but the best way is to lay it up on a heap large enough to do the quarter and throw a coating of mould over it.

It will now be necessary to cover the roots of Rhubarb, Sea-kale, and Asparagus with manure, especially those roots intended to be dug-up for forcing. We have now taken up and potted our Sea-kale roots, and as required they are removed to a house where they can have a little bottom heat. Rhubarb roots will force either in the early vineries or in the Mushroom house. The Asparagus has not yet had a covering of rich short manure; this will be applied on the first favourable occasion.

##### ICE HOUSES.

Every one having houses to fill have been very busy during the last week or two, when plenty of ice could be obtained an inch thick. There are very large ice houses at Barking near London, which are filled at considerable expense to their owners. The small farmers and other owners of horses reap a rich harvest

when the first ice is formed. The ice is stored all above ground; it is all sent to sea in the summer months to preserve fish until it can be delivered at Billingsgate Market. The usual form of ice house for private families is that of the inverted cone. The well is dug on the shady side of an elevated piece of ground, and is further protected from the sun's rays by being planted upon; the well is arched over and entered by a passage from 6 to 12 feet long. The well may be any size, the larger the better, but it should not be less than 6 feet in diameter, and 10 feet deep. The passage is paved with strong flagstones to resist the pounding of the ice with mallets; after being passed into the ice house it is further pounded, until a solid block of ice is formed in the house. The ice is best when it is about an inch thick. The secret in keeping ice is to pound it together so closely that little or no air can penetrate the mass, and it ought also to be kept from the air after the house is filled. The passage to the house ought also to be closely packed with ice.

#### MUSHROOM HOUSE.

Those who are preparing materials for the beds must be fully impressed with the importance of having the manure as dry as possible, for there is no danger at this season of having the beds too dry; if the materials are ever-wet the spawn will probably rot instead of running into the bed. It is seldom that the proper degree of temperature can be obtained with wet material, it either heats too much or becomes rapidly cold; whereas a moderately dry bed, if pressed down, firmly maintains a genial heat until the Mushrooms appear. As soon as they begin to show above ground the bed will most likely require to be sprinkled with tepid water; this prevents the surface from cracking, and produces fleshy Mushrooms which are dry and leathery if the beds become too dry; 55° at night and 60° by day is the best temperature for the house. Admit air daily even if it is in but small quantities. We do not like much artificial heat in the house. For the sake of neatness the roofs are generally slated, but thatch keeps up a far more equable temperature; it is cooler in summer as well as being far more preferable for winter.

#### PINE HOUSES.

During this month and next Pines do not require much attention. All the plants that have fruits in different stages of development must be looked over to see that they do not suffer for want of water at the roots; the soil does not dry very rapidly at this season, but still it must not become quite dry. It is necessary in the neighbourhood of London to wash the outside of the house as well as the inside; there is a certain amount of impurity in the atmosphere, and more so at this season than any other. We are always certain of a deposit of a sooty substance after the thick fogs. It need not be stated that not only Pines but all hothouse plants require all the light it is possible to give them at this season. We have also washed both woodwork and glass internally. No hothouse plants will succeed unless both plants and glass are clean, especially in the winter season.

#### PLANT STOVE AND ORCHID HOUSES.

Even more so than in any other plant-structure would we urge cleanliness in these houses; not a single ray of light should be intercepted, and this is also the best season of the year to eradicate all sorts of insect pests. Thrips are very injurious to Orchids; even *Lælias* and *Cattleyas* suffer very severely from their attacks when the growths are being formed. It is now a very good time to destroy them by fumigating. During the summer months the growths are rapid and succulent, being very easily injured by tobacco smoke. At present this can be applied strong enough to kill the pest without injuring the growths. It is best not to apply the smoke too strong; rather give it three times at intervals of, say, three days. Any plants that have dust or dirt upon the leaves should be carefully sponged with soapy water; we would insist on great care being taken when this is done, as many valuable plants have been permanently injured by the leaflets being bruised or broken when they have been washed.

The most useful of plants at this season are the Orchids, either for cutting from or for decorative purposes. Their showy, quaint, and attractive flowers far surpass the other denizens of the stoves; and the length of time, if they are carefully tended, that they continue is the greatest point in their favour. At present in our warm stove is a plant of Veitch's variety of *Vanda suavis*, the flowers of which have been in full beauty for at least a quarter of a year. Some autumn-flowering varieties of *Dendrobium formosum giganteum* last almost as long; then peeping out from an undergrowth of Ferns are numerous spikes of *Calanthe vestita* in variety, and the noble *C. Veitchii*.

Passing to a house where cool Orchids are grown we have the brilliant *Epidendrum vitellinum*, which has been in flower since July. *Odontoglossums* are always in flower. *O. crispum* is an "all the year round" species; the possessor of a dozen plants need never be without flowers. Some persons may think such plants are expensive, but it is not so. Freshly-imported plants in good health of many of the finest species may be bought in the principal London nurseries at 5s. each. There are of course a few rare species that will always command high

prices, but on the other hand they are always worth the money that was paid for them, or even more if the plants are kept in good health. Deciduous Orchids have now lost their leaves and are at rest; they require very little water at this season—only sufficient to prevent the pseudo-bulbs from shrivelling. The evergreen species must not have very much water, but they require rather more than the others.

We are very careful in watering all stove plants at this season, it is the resting-time for nearly all of them. Our aim is therefore to study the wants of the plants in this respect and when it is necessary to water them to give sufficient to saturate the whole mass of soil, not giving any more water until it is actually required.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Hogg & Wood, Coldstream, N.B.—*Catalogue of Forest and Ornamental Trees, Roses, Shrubs, Conifers, &c.*

Robert Cragg, Rose Nurseries, Car Colston, Bingham, Notts.—*Catalogue of Roses, Pansies, Spring and Summer Bedding Plants, &c.*

Richard Dean, Ealing, London, W.—*Classified List of New and Choice Potatoes.*

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

Books (*An Old Subscriber*).—M. Decaisne's book is costly. Messrs. Trübner, Paternoster Row, could inform you fully.

KEEPING APPLES AND PEARS (*H. A. W.*).—Place them singly on shelves in a dry cold room, and in the dark. Keep out frost and do not wipe them.

ROSE BEAUTY OF GLAZENWOOD (*P. L., Wolverhampton*).—This new Rose is in the hands solely of Mr. Woodthorpe of Glazenwood, near Braintree, Essex, who has not yet commenced selling it to the trade.

HEATING ARRANGEMENTS (*H. L. E.*).—The arrangement of the pipes is, as regards the greenhouse division, correct, and also those of the smaller or stove compartment, only you have too much "stuff" over the pipes to afford bottom heat for striking cuttings. The pipes to give bottom heat should not be covered more deeply than 6 inches with rubble, and upon it place the plunging material for the pots. We advise your having for the propagating bed a frame made with the hinged lights, and this with the greater moisture and closer atmosphere required for propagation will afford speedier and greater certainty of operation.

RAISING CARPET-BEDDING PLANTS FROM SEED (*P. F. S.*).—All the plants you name may be raised from seed, but except the *Amaranthus melanocollis* ruber all the others are best raised from cuttings, as seedlings are too green in the foliage to be of value for effect until late in the season. Dwarf-foliated plants for bedding purposes that may be raised from seed are Dell's Crimson Beet, to be sown early in April in good light soil in an open situation, and transplanted in May in permanent quarters, or sown at the close of April where the plants are to remain; *Cineraria acanthifolia* and *C. maritima*, sow in a hotbed in March and grow-on in heat, pricking-off when large enough to handle, hardening well off before planting out; *Echeveria metallica* treat in the same way as *Cineraria*, also *Oxalis tropaeoloides* and *Golden Feather Pyrethrum*. *Stellaria graminea aurea* and the other plants you name are raised from cuttings.

HEATING WITH INCH CONNECTION PIPING (*Subscriber*).—The 1-inch pipes connecting the 4-inch pipes in the conservatory will answer so long as they remain free; but from the accumulation of sediment and corrosion the waterway becomes closed in a few years, hence we do not advise anything less than 2-inch pipes. They would be better in a covered fine than in drain pipes, which are unsuitable, as they do not admit of access to the pipes in case of need for repairs. Rough plate glass a quarter of an inch thick is the best for the roof of a conservatory with a view to avoid shading the glass.

BOUVARDIA NOT THRIVING (*Bomcedia*).—The sprays sent are destroyed by thrips or red spider, or both, which arises from excessive heat and an insufficiency of moisture. To do well in winter *Bouvardias* require a temperature of 50° to 55° from fire heat, and even this is of no avail if the plants have not been properly prepared for flowering during the summer. Fumigate with tobacco, and maintain a temperature 10° less than that you at present have, with a moister but well-ventilated atmosphere. We shall have an article shortly on the cultivation of these plants.

POTATOES AND GOOSEBERRIES FOR EXHIBITION (*G. F.*).—The best four sorts of each section at the Alexandra Palace Potato Exhibition were:—*Rounds*—Porter's Excelsior, Rector of Woodstock, Model, and Early Market. *Kidneys*—Snowflake, Perfection, Excelsior, and Waterloo. The best Gooseberries at the National Show at Manchester were:—*Red*—Ploughboy and London. *Yellow*—Leveller and Ringer. *Green*—Shiner and Telegraph. *White*—Antagonist and Hero of the Nile.

CONSTRUCTING GREENHOUSES (*G. E. L.*).—We fear we can be of little service to you beyond giving you a few ordinary hints as to the general construction of the house. We presume that being erected against a north wall it will be on the southern side, and a lean-to. The house is narrow; the width would be better increased to 9 feet, and having a 9-inch wall in front this

would leave you 8 feet 3 inches clear space between the walls. The front and end walls we should have 2 feet high above ground, and above this 3 feet of front lights, and the ends sashed for glass above the brickwork; every alternate light along the front to open, and a light along the top the entire length 18 inches wide made to open; both being opened with a crank and lever. Upon the walls you will require a wall-plate 11 inches wide and 24 inches thick, projecting an inch over the wall outside, grooved half an inch from the side or under the outer edge to prevent drip down the face of the wall, and be slightly bevelled outwards from the lights. The front upright may be 7 inches by 8 inches, with an upper plate of 9 inches by 24 inches, and fixed on the uprights an inch back from the face of the wall-plate. The rafters 7 inches by 8 inches rebated three-quarters of an inch deep and half an inch wide for the glass to rest on, and chamfered to half their thickness on the under side. The rafters will not require to be rebated or chamfered only on one side, and those we should have fixed 3 feet apart, mortising the back wall plate, which should be 11 inches by 14 inch, and properly screwed to the wall, the rafters properly tensioned and fitted into the mortice holes at back cut at front so as to fit on to the front upper plate, and so that the rebate for the glass will be level with the upper outer edge of the head plate of the front. Between each rafter have main-bars 8 inches by 14 inch rebated as the rafters, and chamfered on the under side, and fix them so that they will be level with the rafter on the outside, and have a fillet of about 24 inches in width, and so deep as to fill up level with the rebate for the glass. The ends may be sashed for glass with main-bars 8 inches by 14 inch. The door-posts, 6 inches by 4 inches, and be taken up to the end rafters, and the head of the doorway to 4 inches by 8 inches, and continued across the end or ends if you have two doors, preferably at both if you have only one door, and next the wall you will need a plate 4 inches by 8 inches. The top lights 3 inches thick, and the front lights the same, sashed so as to match the roof, hung with 84-inch brass butts. Door, 2 inches thick, flush panelled, upper parts sashed for glass. The timber wall seasoned red deal or yellow pine; the glass 21-oz. sheet, 3ds quality, with quarter-inch lap. We should have a stage 2 feet 3 inches wide along the front, that height from the floor, path 2 feet 8 inches wide, and a step stage to the wall. You will need a capping to cover the joint of the top lights, and a cross-piece acrosswise of the rafters to receive the top lights. We hope you will be able to understand the above details, but as you appear not to be initiated in greenhouse construction we should advise you applying to some of the horticultural builders advertising in our columns, stating dimensions of house you require, and asking for estimate. It would save you much trouble, and might be more economical.

**FORCING ASPARAGUS AND POTATOES IN FRAMES.** (*A Constant Reader*).—You will need to make up a bed of well-sweetened dung and leaves about 8 feet high, well beaten down, and putting on the frame in about a week, when the heat will have risen; and when it declines to a temperature of 78° it may have soil put on 6 inches thick, and when this is quite warmed through put in the Asparagus plants quite closely together, with soil carefully placed about the roots, and between each layer of plants, the crowns not covered deeper than 2 inches, and the distance from the glass should be 12 inches. The temperature of the bed should not be allowed to decline below 65°, but be kept up by linings, and protected with mats over the lights, so as to maintain in the frame a temperature of 55° to 60°. In about a fortnight the shoots of the Asparagus will be fit to cut. The mats in mild weather after the shoots are 4 inches long should be removed by day, so as to give colour and flavour. The Potatoes to be planted in the bed in rows 15 inches apart, and 1 foot apart in the rows, and 4 inches deep, employing sets previously sprouted an inch long. It is well if the sets are not planted until the heat at 4 inches deep has declined to 70°, and it should be kept up to 65° by linings, protecting from frost by mats over the lights, giving air after the hails appear whenever the weather is mild. The main point to be aimed at is a steady growth. Avoid overheating.

**VIOLETS IN WINTER.** (*Idem*).—Plant rooted runners or suckers in April or early in May, in good rich soil a foot apart every way, water well after planting, and in dry weather, keeping clear of runners and weeds; and at the close of September move to frames placed in a dry sheltered situation, and sunny, planting so as to be not more than 9 inches from the glass. The lights to be kept off day and night until frost, and then kept on the frames without air when frost prevails, but whenever the weather is mild air to be given day and night in proportion to the coldness or mildness of the weather. Remove all decaying leaves as they appear, and do not plant closer than 9 inches apart. The plants to be moved with balls. We grow Victoria Regina, which commences blooming in September, and continues up to spring. It is a great advance in size, fragrance, and colour over Oscar, or any single blue Violet yet in commerce. Neapolitan, pale double blue, and very sweet, blooms in October onwards through the winter up to April, and in February the Double Purple and King of Violets, also double blue, with the very large and fine double white Queen of Violets, which is very fine and good, and continues until those bloom in the open ground. With these and Oscar, with the Single White, which we also grow in quantity, we have Violets from September to May inclusive.

**GERANIUMS, PRIMULAS, AND ANASTILIS TO FLOWER IN MARCH.** (*Inquirer*).—The Geraniums and Primulas will be in their blooming pots, and the former will only require to be kept in a light airy position in a cool greenhouse, frost being, of course, excluded, and assisted with weak liquid manure at every alternate watering after the pots are filled with roots, and the Primulas to have a similar position, carefully watered, and have the trusses of bloom moved up to the early part of February; but so much depends on the present state of the plants that without seeing them it is not practicable to give any precise hints. The Amaryllis should be placed in a mild bottom heat the early part of February, and when the flower-buds and leaves begin to grow out of the bulbs remove to a house with a temperature of 80° to 85° from fire heat, affording a higher temperature if likely to be too late for your purpose, or placing in a cool house if too forward. To have plants in bloom at a certain time requires some timely forethought and judgment, which can only be exercised by the grower.

**TREATMENT OF LATE VINEY.** (*Newark*).—The method you propose will not injure the Vines, and it will prevent them from starting until the spring. As soon as the buds start you must shut-up the house in the usual way. It will take them all the season to ripen.

**PEARS NOT BRUTAL.** (*T. P. M. R.*).—Some varieties of Pears if allowed to hang on the tree until they are ready to drop off do not ripen well. It is evident that your examples of Maccrill Egg were allowed to hang too long. You have gained experience which ought to be useful to you next season. You must have allowed Bourré d'Ammon to hang too long. Ours were very good in quality this year. Bourré d'Ammon from pyramids always ripens with us.

**TREATMENT OF FLE-THANE.** (*F. W.*).—If your Fle-thane are out of doors the small orange fruit will drop off, so that it may as well be removed. If under glass the very small fruit of some varieties will ripen early next season. We would not remove them.

**PRUNING FRUIT TREES.** (*W. E. Payne*).—Now is the time to attend to the trees. You will see some instructions as to how it ought to be done at page 516.

**BUNNING BRIARS.** (*G. G.*).—Cut the Briars straight across and put nothing on them. It is on the young side shoots that Bases are budded. The Mammoth stock is named after an Italian professor.

**REMOVING TREES.** (*Jobes*).—A tenant under notice to quit cannot remove fruit trees, neither can he destroy them. He cannot change for laying down lawns, nor can he take away flower roots.

**IMPROVEMENT HEATING APPARATUS.** (*J. H.*).—There is nothing particularly new with a heating apparatus which is so severe a winter as 1874 only required 2 tons 15 cwt. of coal to keep frost from a conservatory; but you say much wood was used in addition to the coal. If not more wood than coal, we do not think the consumption of fuel excessive. Surely you mistake about an "hour and a quarter" action on the boiler with a brick fire being required "before the slightest heat is felt as the commencement of the flow-pipe." There is great difference in stoking. We have known a better fire and more heat had in an hour by one man's stoking than by another in half a day; hence we do not attribute the slow heating to other than slow stoking. There is no advantage in a fire over heating by hot water except for small houses; requiring to be only used in severe weather or dull to exclude frost or dry up damp. We agree with you, however, in utilizing the heat which escapes by the chimney from a boiler furnace, and which may be made to pass along the house in addition to the pipes; but in a conservatory a fire would in many cases be objected to. The great objection to a fire is the excessive heat at the part nearest the furnace, and the liability from cracking of noxious vapours escaping into the house and injuring the plants. There is no difference in heat in point of dryness as given off from the surface of a hot-water pipe or fire, but there is great difference in the temperature, and the greater the heat the sooner is moisture in the vicinity dispersed, and with water on the top the greater the heat the more quickly would it be evaporated, doing more harm than good in winter by the steam generated. It is different with a fire passing through a house after the heat has acted on the boiler surface, there being no danger of overheating the fire surface unless by the firing of accumulated soot.

**THREE COTTA VASES.** (*Idem*).—They are not, if properly made and water not standing in them, injured by frost. We have, however, had them when not well made cracked and splintered during the winter.

**MANURES.** (*Information*).—We have not used that you mention. Write to the preparer and ask him for some names of those who have.

**MAKES OF FRUIT.** (*J. M'Kenzie*).—The Pear should have been in a box. The post-office punches had smashed it. (*W. E. Ashwin*).—1, Windsor Mills; 2, Zéphirin Grégoire; 3, Drap d'Or; 4, Carol's Seedling; 5, Sir William Gibbons; 6, Not known. (*G. F.*).—4, Norfolk Seedling; 9, Delaware; 12, Pearson's Plate; 15, Golden Harvey; 17, Russet Table Pomegranate; 20, Wyden Pippin.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### PRIZES.

We have before us the catalogues of many shows—shows local, agricultural, and open—and we find with hardly one exception that those offering third prizes bear off the palm in the number of entries. We find that exhibitions offering a first prize of 30s. and a second of 15s. do not have nearly so many entries, as a rule, as those giving three prizes of the value of £1, 10s., and 5s., although the loss to the first-named is 10s. in every class. We can readily account for this: So many of the various breeds are in the hands of certain exhibitors, who clear the decks at show after show and monopolise all the prizes and cups; the amateurs and exhibitors in a small way consequently do not enter nearly so readily at the exhibitions which give only two prizes, for they know both these prizes will probably go to certain yards. When, however, there is a third prize offered an extra chance of a place is held out for them; and though the prize may be a small one still it is a prize, and that to many is a great satisfaction, for it pays the entry fee if it does nothing else. This, however, brings up a subject which has been alluded to, as "pot hunting," with the remark that it "will surely kill the poultry classes, the same as we now find in the Pouters; and when amateurs, who are the backbone of the fancy, see the same names winning at every show they very naturally become disheartened, the demand for birds is stopped, entries decrease, and shows become bankrupt." We can endorse nearly every word of this; and though we fear that hardly anything will stop this "pot hunting," still we do think that by giving third and fourth prizes the evil may be greatly lessened, as more inducements will so be held out to those amateurs who are in a small way of business. The "swoopers," as we heard them called the other day, are perhaps cutting their own throats, for we think eventually the demand for high-class birds may decrease when the purchasers find that, even with expensive specimens, they can have no certainty of winning, as the vendors always have something kept back to turn up at every opportunity and to carry off the prizes wherever they are. This evil exists no doubt to a greater extent in some breeds than in others, but the committees of poultry exhibitions can do something to effect an improvement by rather increasing the number of prizes than the value of them; for the actual number of prizes in a schedule

of the present day is much as it was ten years ago, while the number of exhibitors, we should suppose, is considerably more than ten times the number it then was, for every single variety now boasts of a perfect host of admirers. We believe that if the shows took to giving third prizes always, and even fourth and fifth prizes—supposing, too, at first it had to be done at the cost of lessening the value of the first prize—that the committees would be repaid in a very marked way.

Take the Show of Swindon, for example, held a week or two back, and see what a surprising number of entries they had in every class—how their Hamburgs mustered better even than at some of the northern shows, and we are at once shown what a third prize does, which, too, was only 5s. in this case. Swindon had no attractive cups in the various classes—only four for the best pens in the Show among both poultry and Pigeons, the total value of which were only £9 9s., and which can count consequently as nothing in regard to the numbers of entries made. They had no large first prizes either, and yet we find an average of eighteen entries in a class throughout the poultry and Pigeons. This is a capital average, and the third prize was to a very great measure the cause of the success. Taking this late Show at Swindon, then, as an example of the triumph of the third-prize system, we find the total sum received in entry fees for the poultry and Pigeons comes to about £127, while the money spent in prizes comes only to £88; which, too, is supposing that the four cups are given in addition to the prize money. The balance, then, is £44 to the good in entrance fees alone; and we venture to think, that had there been only two prizes of £1 and 10s. the Committee would have been lucky to find that the entrance fees had paid the money expended in prizes. We pick out Swindon as being the last small show of the kind that we have attended; and though the marked courtesy of the officials there may have something to do with the support this Show receives, still we are sure that their third prizes brought the main success.

There are some classes, too, at all shows where it is impossible to do justice with even three prizes to award. Take for example a variety class, where perhaps we may find Malays, Polanders, Sultans, Minorcas, Silkies, and so on, and all of nearly equal merit. The awards to a great extent in such cases have to depend upon the caprice of the judge, and no harsh words should ever be used in reference to the awards in such a class, for the judge is placed in a most difficult position. We would recommend committees, then, especially those who leave many of the more recognised breeds to tabernacle in the "refuge," to have in that class two first prizes, two seconds, and two thirds. We should find such a method of proceeding appreciated by judge and exhibitors, while the entries would come in accordingly. We know it has been recommended before, and in one or two instances carried into effect with success. We should like, however, to see it become general in the interests of the fancy at large.

Although we mentioned, a few lines above, that to enable a third or fourth prize being offered the first prize might be slightly lessened, still there should be no real occasion for this. Some weeks ago we mentioned a tariff for entrance fees in proportion to money spent in prizes, which we thought would answer all ends. We proposed that 8s. should be charged for a £1 first prize, and 1s. for every 10s. afterwards, which would make a 7s. entry fee for a £3 first prize. We still think this would be a very fair and proper scale of charge; and then if a third prize was given to the value of a quarter of the first prize, we believe that committees would find themselves less often in that disagreeable position which is frequently wont to be the case when the settling day arrives. Of course some shows have a great pull in being held in a good neighbourhood, where the station is a junction and the line of rail convenient for exhibitors; but it is the exhibitions that cannot hold out these inducements which should especially study to arrange their entrance fees and prizes in such a tasty way as to draw exhibitors from the well-beaten tracks—that is, if once it is determined to hold a show without losing money; for sometimes we see shows advertised to be held in perfectly inaccessible places, where success can hardly be expected under any circumstances. In conclusion, then, we would recommend committees always to give at least three prizes; for while they would reap the great returns the exhibitors would be pleased, and the arduous work of the judges to some small extent might be lessened in having more prizes to distribute among perhaps an even collection of birds.—W.

### BIRMINGHAM POULTRY SHOW.

THE *Midland Counties Herald* states that, "in consequence of the staff at the disposal of the poultry committee being entirely fresh to their work, several errors occurred in the labelling of the pens and in the despatch of the birds; but the Council hope that, after the efficient coaching which the clerks received at the hands of Mr. G. C. Adkins, Mr. Heape, Mr. H. Mapplebeck, and others, such mistakes will be avoided for the

future. One pen, marked 26, was wrongly labelled add, and the owner wished to claim the money, as he thought the bird would have been sold but for the error; but, of course, the Council could not hold themselves responsible, and he had to be satisfied to receive it back. Another pen, priced in the catalogue at sixty guineas, was unfortunately labelled 'reduced to two guineas,' immediately sold, and since despatched to the purchaser, who, it is hoped, will regard the transaction in the right light, and return the birds.

"In the hurry of despatching such a large number of baskets of poultry one or two of the labels were transposed, and a few people did not receive their own birds, but we believe all the mistakes have now been remedied."

[On such occasions all parties should act kindly, and do as they would be done by.—Eds.]

### DESPATCH OF BIRDS FROM SHOWS.

SURELY it would cause but little additional trouble to committees to have the pens belonging to one exhibitor collected at the close of the show and despatched together. The present system of sending off birds as they are packed, without the slightest attempt at order, and without reference to the place of destination, is productive of serious inconvenience and loss of time to exhibitors, not to mention additional expense.

Let me give my own experience. On a certain day three pens of poultry were due to return from a show not a hundred miles from home. I drove to the station to meet them, when I found that one pen only had arrived. Having put up my trap at the nearest inn I waited patiently the arrival of my birds. At length by the last train that night a second pen arrived, and I had to return home filled with dismal forebodings as to the fate of the third. However, on sending to the station the next day the missing pen was found to have arrived by a morning train, the birds not improved by their long captivity in the hamper. I should add that between the place at which the exhibition was held and the station at which the birds arrived there was no junction on whose broad shoulders the onus of responsibility could be laid. On another occasion four pens came from a show by four different trains; and these are not the only cases.

Now when I say that I live seven miles from a railway station the loss of time, inconvenience, and expense occasioned may be readily imagined. The use of double hampers to a great extent remedies the inconvenience. Still they have a limit of capacity, especially in the case of the large breeds, and there are shows whose committees are wedded to old customs and decline to adopt reforms. With the index which is appended to most catalogues in hand, a steward or stewards aided by porters might be told off to collect the birds of each exhibitor already packed in their hampers, and despatch them to their destination together. Much trouble would be saved to the railway officials at the overcrowded station; the birds would not be detained there so long in the draught and cold, and much anxiety would be spared to exhibitors like myself who have no poultry men to send with their specimens.—SUMNER PARSON.

[It would give very little extra trouble if committees would do as our correspondent wishes, and we know that it would increase the entries. We have heard more than one exhibitor declare he sends only in one class because his pens never came home together.—Eds.]

### CANTERBURY POULTRY SHOW.

WE have come a long way to see this far-famed town and its Poultry Show year by year rising to eminence. In spite of the Kentish snow, deeper this year by far than we have seen in many another county, well are we rewarded. The fanciers of the counties of Kent, Surrey, Sussex and Middlesex (for to these four counties is the Show confined) are certainly most successful and most enthusiastic, for in the generality of classes the display of birds is finer than we see in ordinary open shows. We rejoice that there are still some of these partially-class shows, for here are brought out birds not a whit behind many well-known winners whose owners have not the time or courage to send to the great contest. They are often peculiarly fresh and strong birds, are bought by great breeders, and throw vigour into their strains. The Corn Exchange is a well-lighted and ventilated building, and the temperature excellent. We would suggest that grit in the pens would be far better than sawdust, which the birds eat with their food and suffer from, and that maize should not be given them with such unbounded liberality.

*Dorkings*, especially Silver-Greys, are the specialists of this part of Kent. Fifty-five pens are shown of a high average of excellence. The Silver-Grey classes are the best, and the five-guinea cup for the best pen in the four first classes is justly awarded to a magnificent adult pair of this breed belonging to Mr. O. E. Cresswell. The adult Coloured birds are not a good class; the prizes are well bestowed, but the first-prize cock has

an ugly short fourth claw on one foot. The Coloured chickens (fourteen entries) are very good; the cockerel in the first-prize pen is a capital bird, and so is the pullet in the second. In the class for adult Silver-Greys the cup birds are very perfect all round, the second fair; the third wrongly placed, as the cock has six toes on both feet. The first-prize pen of chickens contains a magnificent pullet, but the cockerel has a partially white sickle—a glaring fault. The second prize is a mistake; the pullet is very red in wing, and both birds have sooty feet; third are fair. Major Plummer's highly-commended cockerel is a very promising bird. *Any other variety.*—Why this class may not compete for the cup we cannot see. Nine pairs of Whites and one of Cuckoos are shown, and we think the class excellent. The cockerel in the first-prize pen is spotlessly white and will make a huge bird. We did not like the second Whites, their combs are not good and their feet not white; we should have put Mr. Boissier's pair second; good single-combed Cuckoos are third. *Spanish* are not many. In the class for adults the first-prize cock is good, mated with a poor hen; and in the second-prize pen the reverse is the case. In the chicken class we admired the first and second prize birds. They are healthy and in good condition, with moderate development of face, and such birds as we should like to breed from. *Cochin-China.*—Mrs. Christy deservedly carries off the palm for Buffs. Her adult pair are first. We fear there must have been a mistake in their entry price (ten guineas), which seems low. They are grand in size and feathering, but not particularly sound in colour; the cock in the second pen is under-feathered but finely shaped. With her pair of chickens Mrs. Christy carries off the china jardiniers; they are a stupendous pair of birds, the pullet dark and evenly coloured. The third pen contains a fine cockerel. *Any other variety.*—Capt. Talbot is first in adults with a magnificent pair of Whites; the cock, however, reposes in an ugly way on his hocks—a position in which we think we have before seen him at shows. Second a well-shaped not large cock and a grand hen; the hen, too, in third pen is very fine. For chickens there are but three entries; fair Whites are first, and backward Part-ridges second and third.

*Brahmas, Dark.*—First in old birds are a fair cock and an exquisitely pencilled hen. Second a nice silvery cock. Third pen contains a cock out of condition; we should have put 111 (Angier) or 118 (Cresswell) in their place. In chickens the first prize contains a beautifully marked and shaped cockerel, though small. Second a fair pair, the pullet under-feathered. *Light.*—The cup goes to a fine pair of adults, their only fault being that the hen's leg-feathering is poor. Second are a large pair; the cock, however, very devoid of neck-marking. Third a smaller but very shapely cock and a handsome hen. In chickens Capt. Savile is first with a good pair, hardly well matched, for the cockerel is exceptionally light in hackle, the pullet very dark and a little spotted on the back. Second are a very large pair, the pullet again marked on back and not well feathered. Third a small hooked cockerel and a very handsome and clearly-marked pullet. In the class for pairs of pullets the clock for the best Dark pair goes to a pen most beautifully pencilled though narrow. First in Lights are a lovely pair, very white, finely shaped but not large. Second and third are also good Lights.

*Game, Reds.*—These classes moderate. *Any other variety.*—First (Foster) Piles, a good style of birds; but a much better pen was shown in the Red class belonging to Mr. Fitz-Herbert; his entries in the two classes having been transposed, owing, no doubt, to the double-basket system. First in Piles (Fitz-Herbert), a grand pen; cock very stylish, matched with a most racy-looking pullet a trifle narrow in the shoulders, otherwise exquisite. *Hamburgs.*—Spangles a moderate lot. Golden-pencilled a larger class with a few better birds. First (Dowker) a pretty pen and in good condition; second (Long) an extremely nice pen. Pen 265 (Hanson) contained a well-marked hen. Silver-pencilled.—(Long) first deserved their position. Second (Norton) also, had the cock been straight in the tail. *Houdans.*—Splendid classes, Mrs. Vallance being first with a pair that would have maintained their position in the largest competition. Messrs. Dring and Lake ran very closely for the second honours. In young birds Mrs. Vallance was again an easy winner. Second (Foster), a good hen. Third (Lake), we liked that gentleman's highly commended pen better. *Crève-Cœur.*—First (Stephens) a fine pair; second (Dring) contained a better hen. *Bantams.*—First and second (Marsh), we preferred the second pen in many points. Pen 297 (Anna), third, not up to the style that gentleman usually exhibits. 311 (Boutcher), pretty but moderate. Bantams, any other variety.—First (Marsh) good in style and colour, cock a trifle coarse in sickles. A good class of Black and White following, Black winning. The classes of *Geese, Turkeys, and Ducks*, with the exception of Blacks, were well supported. In the Black class there were but two entries, and one prize only was judiciously awarded.

*Pigeons.*—There we missed the name of Mr. Martin, who supported the Show so largely last year. Carriers, cocks.—First (Cooksey) a fine bird with good eye and wattle. Hen.—First-

and-cup (Gill) deserved his position. Second (Col. Hassard) a good bird. Pen 568 (same owner), highly commended, rather small, otherwise we preferred him. In the class for young birds some promising specimens were to be seen. The Pouter classes were unusually well filled. Dragons contained ten entries, Mr. Baker being first with a pair of Yellows of sound colour, Mr. Tegetmeier second with a pair of Blues. We should have been pleased to see his pen 625 also in the prize list. Jacobins were a good class. Tumblers not so well filled, the Almonds only mustering four entries. Turbits were a nice lot, and the competition very close. In Owls the prize went to the foreign variety. Fantails.—First and second were charming birds: Mrs. Dring was third with a nice pen. The Homing class of Antwerps was the largest in the Show; the performance of many of them, being announced in the catalogue, afforded a theme for discussion among the visitors.

*DORKINGS.*—Coloured.—1 and 2, R. Cheesman, Westwell. 3 and 4, C. Ratcliffe, Womenswold. *Chickens.*—1 and 2, R. Cheesman. 3, E. Rice, Dame Ours. 4, C. Ratcliffe, A. Rigg. *DORKINGS.*—Silver-Grey.—Capt. O. E. Cresswell, Early Wood. 2, Rev. T. E. Cato, Wyke, Wincage. 3, F. Cheesman. *Chickens.*—1, F. Cheesman. 2, J. Boulding, Fetham. 3, Miss Hogbin, Birlington, Margate. 4, Mrs. Waicher, Major Plummer.

*DORKINGS.*—Any other variety.—1, O. E. Cresswell. 2, J. Ivory & Son, Dorking. 3, A. Chalwin. 4, E. A. Boissier, Major Plummer. *SPANISH.*—1, H. Brown, Putney Heath. 2, J. Francis, Tonbridge. 3, C. W. Hammond, Ashford. *Chickens.*—1, A. Marchant, Fetham. 2, A. Howson, Streatham. 3 and 4, J. Francis.

*COCHIN-CHINAS.*—Buff or Cinnamon.—1, Mrs. A. Christy, Falconhurst. 2, G. P. Ladd, Canterbury. 3 and 4, W. White, Ridgeway, Canterbury. *Chickens.*—Jardiniers, Mrs. A. Christy. 2, T. W. Anna, Upland. 3, Mrs. A. Christy. 4, G. P. Ladd, L. Collard. 5, A. S. Paine, H. Stephens, G. Dowker.

*COCHIN-CHINAS.*—Any other variety.—1, Capt. G. F. Talbot, Edinham. 2, R. A. Boissier, Fenshurst. 3, Mrs. Brasse, Battie. 4, Mrs. White, Capt. G. F. Talbot. 5, Col. F. C. Hassard, Miss E. Mansel, H. A. Rigg. *Chickens.*—1, R. A. Boissier. 2 and 3, Col. E. F. Lake, Canterbury. 4, Rev. J. D. Peake, Laleham Vicarage, Chertsey. 5, W. Jacob, Shepherdwell, Dover. 6, J. Long, Ravenscroft, Barmet. 7, F. Lake, Dr. G. A. Angier, J. B. Lambier. 8, Rev. J. P. Wright, O. E. Cresswell. *Chickens.*—1, J. Long. 2, M. Sandford, Martin, Dover. 3, W. Jacob. 4, T. Harvey. 5, N. Edgill.

*BRAHMA ROOTS.*—Light.—Cup, Rev. J. M. Rice. 3 and 4, Capt. W. Saville. 5, E. Bird, Rev. E. T. Scott, G. Dowker. *Chickens.*—1, Capt. W. Saville. 2, H. Stephens. 3, F. Cheesman. 4, Rev. J. M. Rice. 5, Bird. 6, Pitt, Capt. W. Saville. 7, W. Foster. 8, O. E. Cresswell.

*BRAHMA ROOTS.*—Light and Dark.—Pullets.—Cup, Capt. W. Saville. Chick. Miss E. C. Shuter. 3, Dr. G. A. Angier. 4, E. Bird, Lady Oxenden, W. Jacob. 5, H. Stephens, F. B. Cobb, Rev. J. D. Peake, J. A. Beames. *GAME.*—Black-breasted or other Reds.—Cup and 3, V. Sandford. 2, F. Ward. 4, J. Long, V. Sandford. 5, W. Foster. *Chickens.*—1 and 2, F. Ward. 3, W. Foster. 4, J. Ekan.

*GAME.*—Any other variety.—1, W. Foster. 2, C. J. Plumptre. 3, J. Chittenden. *Chickens.*—Cup and 2, G. H. Fitz-Herbert. 3, C. J. Plumptre. 4, W. Foster. 5, E. Rice. 6, J. Plumptre.

*GAME.*—Any other variety.—Cock or Cockerel.—1, G. H. Fitz-Herbert. 2, E. Akhurst. 3, F. Ward. 4, J. Chittenden. *HAMBURGERS.*—Gold-spangled.—1 and 2, J. Long. 3, J. Metcalfe. *Silver-spangled.*—1 and 2, J. Long. 3, A. Stokings. 4, J. R. Lambier.

*GAME.*—Black or Gold penicils.—Cup and 3, G. Dowker. 2, J. Long. 4, C. J. Plumptre. 5, A. H. Watson, J. Long, E. White, J. Chapman, G. Jackson, F. Hanson, O. Thompson. *Silver penicils.*—1 and 2, J. Long. 3, J. Long. 4, J. Long. 5, Houdans.—1, Mrs. Vallance. 2, F. Lake. 3, W. Dring. 4, F. Lake, W. Dring. *Chickens.*—Cup, Mrs. Vallance. 2, E. J. Foster. 3, F. Lake. 4, F. Lake, W. Dring. 5, Mrs. Vallance, M. Sandford, P. Hanson.

*CRÈVE-CŒUR.*—1, H. Stephens. 2 and 3, W. Dring. 4, Miss A. Sharp. *GAME BANTAMS.*—Black-breasted or other Reds.—Cup and 2, W. S. Marsh. 3, T. W. Marsh. 4, J. E. B. Smith, W. Boucher. *Any other variety.*—Cup, W. S. Marsh. 2, F. Ward. 3, Master Sandford. 4, G. H. Fitz-Herbert. 5, J. Symonds, F. Akhurst, Jun.

*BANTAMS.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

*GAME.*—Black or White, Clean-legged.—1, J. Ware, Jun. 2, Mrs. Lambert. 3, W. H. Williams. 4, W. White, Lady Oxenden, J. R. Lambier, C. W. Gwynne. 5, G. P. Ladd. *Any other variety.*—1, Capt. G. F. Talbot. 2, H. Cooper. 3, R. A. Boissier. 4, L. G. Morrell, H. Stephens.

### GUILDFORD SHOW OF POULTRY, &c.

THIS was held in the White Horse Hotel Auction Mart on the 19th and 14th inst. The awards are as follows:—

#### W. GOSWELL.

**Guzzards.**—1, W. Messenger, Wodsworth. 2, Mrs. Radclyffe. 3, T. Baker, Goddards. 4, T. Land, Tyng. 5, S. Hider, Woking. 6, W. Messenger.

**Turkeys.**—1, G. H. Langford, Lockport. 2, Rev. N. J. Kidley, Newbury. 3, Mrs. M. Marshall, Goddards. 4, F. Ward, Maidstone. 5, Mrs. Radclyffe. 6, Countess of Lovelace.

**Fowls.**—*Carriers*.—1, A. T. Skinner, Guildford. 2, F. Fawcett. 3, O. R. Crosswell. 4, J. E. Casper, Guildford. 5, A. T. Skinner. 6, O. R. Crosswell.

**Judges.**—Mr. J. Baily, Mount Street, London.

### PROTECTING AND FEEDING BEES IN WINTER AND EARLY SPRING.

It seems likely enough that we are going to have a winter of more than ordinary severity and of some duration, if we may judge from the gradual way it has been coming on and the steady increase of the cold. Bee-keepers, therefore, should be on the alert, and do what they can to guard against disaster and consequent loss from whatever cause.

Foremost to all persons whose stocks are well supplied with food is the due protection of them from excessive cold. Cover them over with any warm material that is to be had; straw is best for the bell-shaped hive. Make the harkles as thick as possible, and tighten the straws together with hoops of iron or wire, so as to shoot off all rain and melting snow. As for dry snow it is about the best natural protection the hives can have, and is as good as a warm nightcap to them. My bees being all in boxes I have had square or oblong caps of old thick druggist made to slip over them. These I make to fit close to the hives by tying them round with string. Take care at the same time to keep the entrances open, but narrow them as much as you can, taking care to allow at least two bees to pass out abreast, and ever and anon as soon as milder weather comes open them wide

and clear away all dead bees you can reach on the floorboard inside with the help of a bit of curved iron wire.

Next carefully watch the decreasing weight of your hives, and give the bees a little warm liquid food immediately on the return of warm open weather whenever, especially after a week's frost, they begin to fly abroad. Those persons who fed late before this frost began will find the hives thus fed in better health as a rule, and less liable to die of starvation, than stocks which are very strong in food but which have not been lately fed. The explanation is simple enough. In the former case the combs in the centre of the hive are well filled with their recent supplies; in the latter the bees in many cases will have devoured their stores at the centre where they are huddled together, and will often perish there of starvation from the impossibility of their bringing in enough food from their distant stores owing to the cold. This is oftentimes the secret of so many hives in spring being found to have perished, although there was plenty of sealed honeycomb in them. It will not be found amiss in such circumstances—I mean where there is any doubt on the point—to bring the hives in before a warm kitchen fire to pass the night in the warmer temperature. The entrance hole, of course, must be stopped, but ventilation given by means of perforated zinc plates or blocks. The grateful humming of the bees within will tell of the good work going on there. In a few hours they will have carried away into their nearer cells many pounds of that which is to them the staff of life. This may be done at any time in the coldest weather.

Besides this, we earnestly advise all stocks to receive a pound or two of honey or sugar syrup immediately on the first return of mild weather. Be ready with your food prepared for all such emergencies. We must have rich honey seasons coming. Is it not well to be always in readiness for them?—B. & W.

### BAR FRAMES.

THE question put by "ZENAS" is now occupying the attention of many bee-keepers and hive-makers in England—viz., "the placing of bars so as to prevent their being glued together by the bees." If so glued together, as is often the case, their

Fig. 118.

removal is somewhat provoking to the bees and dangerous to the bee-master. Many efforts have been made of late, and many are still being made, to prevent the bees from cementing the bars to the hive and making them easy of removal. Some of the efforts made have resulted in improvements. The making of bar-frames has been simplified, their price lessened, and their removal made more easy. The following sketch (Fig. 118) of two bars laid across the top of a hive, will enable "ZENAS" to form a pretty accurate idea of what we deem the best, most simple, and easily handled frames yet invented. The bars project beyond the hives half an inch, and the crown lid should project a little beyond the ends of the bars. The projections of the bars as seen on the sides of the hive (back and front), keep the combs half an inch asunder, which is about the proper distance.

"ZENAS" puts another question in these words, "Are hives on the moveable-comb principle intended for storing or for drain-

## WEEKLY CALENDAR.

Day of Month Week.		DECEMBER 23—29, 1875.			Average Temperature near London.			Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.	
Day.	Night.	Mean.	m.	h.	m.	h.	m.	h.	m.	h.	Days.	m.	a.		
23	TH		44.1	81.7	87.9	7	af	8	53	af	8	17	af	0	857

27	M	SUNDAY AFTER CHRISTMAS.—ST. STEPHEN.	48.0	29.7	36.4	9	8	55	8	86	8	59	2	30	861
28	TU	Bank Holiday.	42.6	29.5	36.0	9	8	55	8	21	9	0	4	1	862
29	W		48.9	33.0	38.5	9	8	56	8	54	9	12	5	2	863

From observations taken near London during forty-three years, the average day temperature of the week is 48.4°; and its night temperature 30.8°.

## A CHRISTMAS GREETING.

CHRISTMAS has a wonderful power over an Englishman's mind and heart. In the dread Crimean winter twenty-one years ago, amid all sorts of miseries, our soldiers did their best to keep Christmas. Then there are the thousands of Englishmen with their feet to our feet in Australia, with a different sky above them, different stars to look at, no "Charles's Wain" over their housetops; they cannot as we do

"Watch the Pleiads, rising through the mellow shade,  
Glitter like a swarm of fireflies tangled in a silver braid."

Who, instead of looking

"On great Orion sloping slowly to the west,"

look on the Southern Cross. These our Australian brothers, emigrants from old England, with a sky above unlike our sky—with an earth beneath with its animals and birds so different to ours, and, harder still to bear, with a total change of seasons to live in: our summer their winter, our winter their summer; their midsummer day our midwinter time in feeling, and their Christmas day one of the hottest days of the year. A young man in North Queensland wrote to me last Christmas day in the words, "Here I am eating my Christmas plum pudding, and beating off the huge mosquitoes from my face; for in spite of the difference of weather, I would keep my Christmas day and think of the dear ones at home." Oh! what a power has Christmas over Englishmen. At the Reformation many feast days and holidays were abolished, and the "gospel of idleness" no longer preached; but Christmas remained, and remains dearer than ever—a holiday time, a social time, a time for pleasant greetings. This is well, but "the gospel of idleness" has of late years been too much preached again and over-much of holiday time talked of. Give the labourers and mechanics higher wages to meet dearer times; but as yet, in multitudes of cases, shorter hours of work have come to mean longer hours at the public house. Educate to a higher standard, and higher pleasures will be loved; but preach not too much the gospel of idleness of over-holiday-making, but cling and cleave to and keep rightly Christmas-tide, and greet lovingly all around you.

There is another way in which Christmas time may be viewed. It is the last part of the old year that is thought about. The year is about to leave us in these latter days of December, and so up comes Father Christmas and puts out his hand very cordially, seeming to say, "Well, if the year, O men! has not been a very good one, let us, nevertheless, part friends; let us shake hands and hope for a better." Truly the past year has not been a good one for the gardening world. A terribly severe winter did not bring us the wished-for early genial spring, but cold and wet, floods and storms; and then when summer months came, scarcely came summer weather. Not the glorious quiet warm time, scarce a leaf stirring, the trees knee deep in fern, the cattle standing in streams, the bright Geraniums budding and blooming, and glowing in

the sunshine, not growing for ever with huge leaves as this year.

"Father Christmas, we gardeners take your hand and press it warmly, and greet you kindly, but please speak to the clerk of the weather and provide a better year for us in the one that's coming."

Next let me turn to gardening advances. First and foremost this year has brought us the new edition of our Doctor's "Fruit Manual." This not only a standard work and showing such accurate knowledge and diligent research, but is so interesting. "Sir," said grand old Dr. Johnson, "Dr. Gollsmith will write a natural history and make it as interesting as a fairy tale." This is what "our" Doctor has done with fruit history. The book is on my shelf of favourites, and is already pencil-marked and thumbbed, and threatens to want binding from constant reading of it; and as with me so I doubt not with many others.

Fruit culture needs more attention than it receives, and from all classes. In farm and cottage gardens it is now common, even in very out-of-the-way places, to see standard Roses of named varieties and prize quality; but look at the Apple trees and other fruit trees of such gardens. These are generally very old, very cankered, very mossy—all the upper roots cut by the spade, and so the lower penetrating deeper and deeper, and the trees growing or declining worse and worse. Such trees too! so straggling, shading much ground, and injuring all crops; unsightly, half useless, scrubby ugly trees, but kept in the gardens because they have been there so long. Now, I hope in a few years to see pyramid fruit trees in such gardens—pretty trees, early-yielding trees, and trees that do not shade valuable land. Said a man of more than ordinary knowledge to a man in his forties who was thinking of planting fruit trees, "It is too late in life for you to do that." Indeed it is yet to the general world an unknown thing that Apples on the Paradise stock and Pears on the Quince stock produce fruit-bearing trees at once. "Plant Pears, plant for your heirs," that is old-world nonsense now. Plant them and gather the fruit yourself the year after next.

One great means of causing improvement in the humbler class of gardeners is for the upper classes—gentry, clergy, and others, to encourage district horticultural shows embracing many parishes. The one in which I take a personal interest in the district in which I live has in its progress gratified me much. At the first show four years ago the cottager classes were poorly filled, and the specimens were poor too, but four years have shown a great advance—the classes well filled, and the specimens far finer. They have shown a greater improvement than any other classes, but the fruit is still poor, the varieties of Apples and Pears the older and the commoner, and scarce a dish where beauty and utility were combined. This will continue to be the case until pyramid fruit trees find their way into the humbler gardens as choice Rose trees have already found places there.

The mention of Roses reminds me of another advance—the estimating the beauty of a Rose by its perfume.

Here is a return indeed to old days, and advancing by going back is often the truest advance. Three centuries since a Rose was chiefly valued for its perfume. "A Rose by any other name would smell as sweet," wrote Shakespeare. It was the scent and not the form that weighed with our forefathers, combined with medical properties. The older flowers are the sweeter flowers as a rule; and when the present Premier's heroine, Lady Colisande, in "Lothair," had a garden of scented flowers, they were almost all old-fashioned. Flowers are beautiful to look at, but the bouquet is doubly valued when the finely-chiselled nostril is gratified as well as the eye.

There is, too, another advance by going back which strikes one—namely, the revival of a love of button-hole bouquets, which our ancestors called posies. Says Christopher Marlow, writing in the sixteenth century, in the character of a shepherd singing to his love—

"I will make thee beds of Roses,  
And a thousand fragrant posies."

The fashion for button-hole flowers had well nigh died away. An old buck or two among the gentry kept to it, and a flower-loving peasant here and there appeared at church with a posy half as big as a Cauliflower, and one wondered any button-hole could carry it. But now the pretty custom has come back again; and in the heart of the City of London, specially on a Saturday afternoon, stand rows of flower girls proffering, and not in vain, a button-hole posy to the city clerks on their leaving their offices earlier, the posies being carefully taken and kept in water for the Sunday adornment.

Flowers of perfume are doubly valued as decorations if blended with a spray of graceful Fern. The cultivation of sweet-scented flowers is sure to advance, and we shall have again "many a Carnation feeding with summer spice the humming air." Bacon speaks of those who gather "flowers being withal sweet and sightly." The "sightly" has been too much regarded minus the "sweet."

But not alone do we in "our Journal" dwell on flowers and fruits. Many open the *Journal of Horticulture* for the latter columns chiefly, for to them the bird and the bee are more attractive than the fruit or the flower. Their pleasures arise from harmless hobbies. Well says a recent writer in a first-class periodical—"Of course, by becoming a hunter of rarities a great deal of money may be spent; but that is a pursuit which, however respectable, is generally most enjoyable when the means are limited. When Charles Lamb screwed up his courage to give a few shillings for an old dramatist, he had more pleasure of his bargain than the rich man who would give as many hundreds. As some people have found rat-killing as amusing as tiger-shooting, so the poor collector gets as much fun out of his pursuits as his rival with a bottomless purse. And the various forms of curiosity-hunting, whether the objects be the old masters, or rare books, or china, or autographs, or pigeons, are about equally interesting." These words I hold perfectly true. The poor man's hobby gives him as much pleasure as the rich man's—I am half inclined to think more, because the objects loved are fewer, and love concentrated is the strongest. If a rich man has been able to buy some grand picture, his joy is not much, if even as much, as when the fancier has obtained a long-desired bird which he holds lovingly in his hand with his eyes full of admiration and delight. It will be noticed that the writer above quoted mentions "pigeons." This would not have been the case a few years since, but our two great Shows in the two London Palaces have drawn an amount of notice upon the fancy which many provincial shows could not have done, for London leads thought and always will.

I hold, too, that, now wages are higher, the lower classes more and more need innocent hobbies for their spare hours, particularly as these are more numerous. If the unbending of the mind does not take an innocent turn there is more harm to be dreaded from idle than from working hours. The gospel of idleness is a baneful gospel—nay, no gospel, but bad news to men unless they can well employ these idle hours. Whether it is the town artisan or the country labourer—whether the temptation be the town's attractions or the country's dullness, there needs a safety-valve, an outlet for the lesser faculties. Happy that man who can turn to his garden and find his pleasure there; and it is best to have a hobby within a hobby—even in a garden some pet variety of fruit, or vegetable, or flower. If you have you will soon feel the advantage. But a garden all do not care for, and all cannot have. But a back yard may be peopled with birds—poultry or pigeons, or an

inner room be alive with canaries. If people live in the country and have not country tastes their life is apt to be dreary at times; but love and understand the book of nature—I ought to have written "understand and love," for love comes from knowledge—then you will never be unhappy.

I am fond of hearing and recording any acts of kindness; let me write down one which occurred within my own knowledge. Early in the bitter, bitter cold of the present year a clergyman with a large and grown-up family was stricken down in a few days. The news of death and the illness coming to many at the same time. They had been a family of garden lovers, thinking their home and their garden sweeter than aught else. There was a group of daughters most active among their poor neighbours, hard and warm-hearted workers. It so happened that the family removed from a sweetly rural spot to the thick air of a manufacturing town, where garden for them there was none. Each week their village neighbours took turns in sending to their late clergyman's widow and daughters a hamper of vegetables and fruit from their gardens, believing, and rightly believing, that no vegetables or fruit would taste half so sweet as those from their loved village. This went on from week to week till the village feast came round, and then the poor begged that the hamper might be double the size for them to enclose their offerings of flowers from their gardens—flowers the sweetest of all presents, and which the poorest cottage-dweller may offer, and the daintiest lady in the land be pleased to receive. Can you not easily understand, good reader, the joy the opening of that hamper would give? This posy from that tiny garden, cut from plants known to the receivers; here a bunch of Roses from a porch, there some Stocks from a wayside garden, all known, all remembered.

But I must hasten to a conclusion. What was the angelic greeting on the first Christmas morning? "Peace on earth and good will to men." When man was innocent and at perfect peace with all he lived in a garden; and though innocence is lost, yet peace is often found in a garden. Its little plot is the child's delight; his garden is often the old man's last love. Business is too much for him, that he has resigned. Travelling too wearying, that he has given up. He again, indeed, goes his journeys, but only in his easy chair, and prattles there of former scenes by land and sea. Company he cannot enter into, its late hours do not suit him, and conversation passes him, and the days of quick reply and keen intellectual talk are over. But there is something left him to enjoy—his easy-of-access, pleasant garden, where he may rest in sunshine or shade as he wills, and husband his strength and enjoy himself, watching and being interested in each crop as it ripens, each flower as it unfolds its blooming beauty. A garden is man's first love and his last. It promotes "peace," and an interchange or giving of its products creates "good will." Grand words, blessed greeting, "Peace and Good Will" sounding over Christendom, heard all over England! And may their meaning be better understood as each Christmas comes round. In the words of an American poet—

"I hear the bells on Christmas day  
Their old familiar carols play,  
And wild and sweet  
The words repeat,  
Of peace on earth, good will to men.  
The wrong shall fall,  
The right prevail,  
With peace on earth, good will to men."

—WILTSHIRE RECTOR.

## PLUMS.

PLUMS are so popular that not one word of eulogy is necessary to attract notice to them, or to promote their more extensive culture, otherwise than may unavoidably occur in describing the merits of some kinds that are not so well known as they deserve to be. Possessed of wonderful vitality, very prolific, perfectly hardy—such choice kinds as Transparent Gage ripening perfectly upon orchard trees in the north—not very liable to suffer from the attacks of noxious insects or blight, of easy culture, trees possessing all the luxuriance of a free, wild, unchecked growth, or amenable to pruning and training after the most severe rule of art (advantage, if any, being rather in favour of the untrained tree), that here also an elaborate cultural essay is uncalled for.

When I first began the culture of cone-shaped Plum trees it was with a strong impression that it was no easy matter to impart that form to them, and that a really handsome sym-

metrical specimen would be the exception rather than the rule. Most gladly, therefore, do I record results totally opposed to this erroneous idea of mine. The difficulty, if it occurs at all, does so at the beginning; and whenever a want of balance, arising from a weakly growth in the lower branches and excessive vigour in those near the top, is perceptible, it is invariably owing to a bad start, or, in plainer words, to the mismanagement of the tree in the earlier stages of its growth. A want of decision at the time of planting often leads to failure. Arbitrary rules have a mischievous tendency when applied indiscriminately, but in this instance it should be insisted upon that when a young Plum tree is not well furnished with strong branches at its base at the time of planting, its top must be sacrificed and the stem reduced to a length of 18 inches. Then, if the planting is well done, shoots will break forth during the first season of growth, and disposed in a manner to form a perfect tree. Thus do we lay the foundation and insure the success of our work; the central stem rises above its youthful rivals, putting forth other branches, tier above tier, till the structure is complete—a perfect cone. The formation from lateral growths of spurs clustering with fruit buds goes briskly forward, and a few brief seasons bring to the work its full reward in that best of all forms a full crop of fruit. Apart from this, the tree is really a reward in itself—a certificate of merit of no mean order—a symmetrical form that is always a pleasant sight, exemplifying economy of space with the maintenance of a just balance in every part.

Most kinds of Plum trees are so distinct in habit of growth and general appearance as to be easily recognised. I have closely observed these peculiarities, and will note a few of them in the following estimate of sorts.

**Green Gage.**—Of all Plums the Gages most worthily stand first, and our old friend the Green Gage is such a general favourite that it might not inaptly be quoted as forming an the common diversity of taste. It good qualities exception to are admitted by all. Some flourishing young pyramidal trees which came nicely into bearing this year have a clean, regular, free growth, somewhat slight, spreading with a gentle curve upwards. The fruit of this variety is, however, greatly improved with the age of the trees, of which I will quote an example on a future occasion.

**Purple Gage.**—A pair of fine symmetrical trees of this valuable variety have a more sturdy erect growth and more compact habit than the Green Gage. The branches are also more thickly set with spurs. The fruit has the full rich flavour of the green variety, is of similar form, and of an attractive mottled purple hue. It hangs well upon the tree, and may be kept in the fruit-room for some weeks in its slightly shrivelled condition with little loss of flavour, thus forming a most serviceable adjunct to the dessert in autumn.

**Bryanston Gage.**—These are strong vigorous trees, having a peculiar erect growth with very numerous spurs, having a close resemblance in general outline to Oullins Golden. The fruit, which is produced in great abundance, is very large—much larger than the old kind, greenish yellow in colour, and of most delicious flavour. An excellent Plum which all should grow.

**Transparent Gage.**—This is another of the large type of Gages. The fruit is pale yellow, tinged and mottled with red on the side exposed to the sun. It was ripe this season in the second week of September, and is so delicious that it has been termed "superior to all other Plums." Certainly its excellence in this respect is so great that it must satisfy the most fastidious palate. I have it trained to a wall and also in an orchard. The growth is strong and free, but the trees are hardly large enough to enable one to judge clearly of peculiarities of habit. Mr. Rivers says that this variety and Reine Claude Boddart are the finest of the Gages. This last kind and M'Laughlin's Gage I planted last season, but they have not yet fruited.

**Jodotne Green Gage.**—This variety has disappointed me. It is wonderfully prolific, and the fruit is handsome, of good form, and with so much blue colour upon the exposed side that its title of "green" strikes one as a misnomer; but it has so little flavour as to be positively insipid. I have either a spurious kind, or the assertion that it is equal in flavour to the old Green Gage is a mistaken one. A couple of pyramids which I have in cultivation under this name have a thin spreading growth, imparting a loose and somewhat ragged appearance to the trees, which are, notwithstanding, tolerably symmetrical.

**Oullins Golden.**—This has a very stout, vigorous, yet

compact habit of growth, well set with spurs, not at all spreading, but remarkable for the singular manner in which every branch springs directly upwards from the stem at an acute angle. It is probably owing to its excessive vigour the young trees are so much behind other sorts in producing fruit. The fruit is very beautiful, very similar in appearance to the Washington, a rich yellow tinged with crimson on the sunned side. A fine fruit of sweet and pleasant flavour, ripening early in August, but which may sometimes be seen in good condition as late as the first week in September.

**Royal Hâtive.**—I have heard this termed a good dessert Plum, but I have not found those which I have tasted at all equal to my standard. The trees are very handsome, with a distinct spreading habit, and a free growth of medium strength.

**Kirke's.**—The trees of this kind are of good form, and have a tolerably vigorous spreading growth, well furnished with spurs. My note of it in the fruit book for this year states that the fruit is large and slightly oval in form; colour deep purple, almost black, with a fine bluish bloom, sweet and juicy, but more valuable for cooking than for the dessert. Good crop. Trees vigorous.

**Belgian Purple.**—A tree of good form, with a free strong growth well set with spurs. It is a prolific sort, with dark purple medium-sized fruit, mottled with red and having an attractive bluish bloom. It is very juicy and rich in flavour, and is said to be ripe by the middle of August, but it was not ripe this season till the first week in September.

**Late Rivers.**—This kind surpasses all others in the vigour of its growth, quickly forming a large spreading tree. It is very prolific, and its sweet juicy fruit is highly valued for its lateness.

**Blue Imperatrice** is one of our most valuable late autumn Plums. Trained to a north wall its oval-shaped richly-flavoured fruit may be had in perfection very late, for it hangs a long time upon the tree. I like to plant it on a northern aspect with the Morello Cherry, both fruits being of the greatest value for the splendid supply which they afford throughout October.

**Early Rivers.**—A culinary Plum of great value, ripening early in July. Its tolerably large, oval, purple fruit is very sweet and juicy, and is produced in great profusion. The trees are very handsome and vigorous, with a free, strong, and erect habit of growth. Quite distinct from other kinds.

**Prince Englebert.**—Both the trees and the fruit which they bear are very distinct, the trees being remarkable for the sturdy proportions which they so quickly assume, and their close erect habit of growth. The splendid oval-shaped fruit is very large, of a deep purple colour with an attractive bluish bloom, and, what is more important, it is most valuable for all purposes of cooking and preserving.

**Denyer's Victoria.**—The growth of this deservedly popular sort has a spreading yet upward tendency, forming vigorous trees of symmetrical outline. It is very prolific, and the fruit makes a delicious preserve, and is one of our best cooking fruits. Red in colour, oval in form, and very sweet and juicy.

**Lafayette.**—This is a late September kind, forming handsome trees, is very prolific, and is so sweet and juicy as to be valuable both for dessert and cooking. A most useful sort, cropping well this year.

**Rivers's Early Damson.**—This forms a neat, compact, and well-shaped tree, the tolerably free growth being well furnished with spurs. It is very prolific, and is most valuable from the fact of its sweet and juicy fruit ripening so early in August.

**Cluster Damson.**—Doubtless so called from its extraordinary fertility, the branches being literally clothed with fruit in such dense clusters as to render the process of picking a somewhat tedious business. The growth is stout, vigorous, thickly set with spurs, interspersed with a few thorns in its young state; tree somewhat spreading and irregular in habit, and with dark-coloured bark. This kind and Early Rivers are those which I can recommend for giving an abundant early and late supply of fruit. Preference is frequently given to the Shropshire Damson for preserving, for which reason I have planted a dozen of it. They are forming pretty compact little pyramids, but there is a slender delicate habit about them that is in striking contrast to the sturdy vigour of the Cluster.

In giving these estimates of fruit in detail my object is not only to show which, in my opinion, are the best kinds, but to describe each kind sufficiently to enable others to gain tolerably correct ideas to guide them in purchasing and planting, for it should never be forgotten how widely different are individual tastes. What Brown likes Jones detests; the object of

Smith's fondest regards is Green's abhorrence; and therefore it would be as unwise as unprofitable to attempt to dictate. Rather would I try so to teach so as to induce independent thought—to set forth individual traits and characteristics—to show clearly which of the varieties have proved the most useful, and why—to induce others to judge for themselves; in a word, to offer the results of practice and experience.

In looking over these notes I find that no mention has been made of upwards of a dozen kinds of Plums, good and bad, which I have in cultivation; enough good kinds have, however, been noted to select from, and I need not, therefore, add to the length of this paper.—EDWARD LUCKHURST.

## NEGLECTED FLORISTS' FLOWERS.

### THE RANUNCULUS.

In the round of favourite flowers grown by florists of a generation since, there often used to come in due succession between the Pink and the Plectee, and in most refreshing contrast to all before and after it—the Ranunculus. Now its place in such a garden circle is often vacant. Not many Tulip cabinets have now their few drawers at the bottom for Ranunculuses. It is a great pity, because the flower is full of capabilities and properties attractive to the florist. It possesses great command of colour. In the self varieties there are crimson and purple blacks; scarlet, red, rose, pink, and white. In yellow, orange, lemon, cream; also white. There are classes of white and yellow grounds with tips and edges, mottles and stripes of various colours, usually some shade of purple, brown, rose, and red, and in addition to these are some curious roans, grey, and red, that are a fancy dress peculiar to the Ranunculus.

One of the chief charms of this flower, particularly to a florist, is that it is very sportive and vigorous from seed, so much so that a seedling-bed is, perhaps, the great surprise and charm of Ranunculus-growing. Even the most double exhibition flower will frequently afford a seed head when fully expanded, but very seldom any stamens. Pollen must, therefore, be obtained from well-shaped and coloured semi-doubles that afford it freely. Good seed somewhat resembles scales or flakes of bran with a slight brown germ set in the middle. It is very delicate, and like seed of the Auricula is better left uncovered by any soil, and the soil kept generally moist by a sheet of glass over it. Sowing may be done at the time the old tubers are planted—about the end of February.

The Ranunculus has, no doubt, an ill name for being a crotchety, ill-tempered old flower, a punctilious tuber requiring everything to its own good liking, or else declining to bloom. The plant is, indeed, particular in some of its requirements, but troublesome in none. It is exact but not exacting. It requires precisely its inch and a half underground, otherwise the new tuber which is naturally formed over the very neck or woolly crest of the old one will endeavour to rectify matters by diving down or coming up by means of a sort of underground stem, dropping several of its claws in the course of it, and making an awkward if not weakened root.

At planting time I always wet the tubers twenty-four hours beforehand; they then swell marvellously, and do not literally get up and walk out of bed, as they often do when planted dry. Moistening them also enables one to detect any diseased or rotten claw, which ought to be removed, but cannot be easily detected in a dry state. The claws when thus swelled are not brittle or liable to be snapped off so easily at planting. Knocking off a healthy claw is so much loss of stored-up strength, and it is worth while to be careful. Another emphatic demand of the Ranunculus is a firm bed for growing in. If I were doomed to take those forced and dismal walks called "constitutional," I would never forget to take some over my next year's Ranunculus bed. It would be a walk "with an object."

There are matters which the Ranunculus is more particular about than soil, though it likes that good and hearty. Mr. Tyso, the present representative of this flower, most wisely because most naturally, says that a bed made up of turfy sods from a strong pasture where the Buttercup grows will suit our member of that family, the Ranunculus. This is the best advice that can be given where the native soil of the garden is not a deep retentive, yet well drained loam, or one that will grow a hearty Cabbage. Enrichment of cow or hotbed manure may be used, but it must be truly well decayed, and the bed is far the best when made up in October.

Again, another vital point in Ranunculus culture is a well-aired bed for sleeping in—that is, a scrupulously dry storage

when out of the ground. This tuber has literally to be shelved for more than six months out of twelve, owing to its foliage, which would naturally spring afresh in autumn, not being hardy enough to certainly bear our winters. It is therefore forced to rest from about the third week in July to the third week in February. Where there is the slightest dampness the naked tubers are peculiarly liable to contract blue mould at the neck. It is generally fatal, disorganizing the claws and eating into the heart, and when in the ground the whole structure rots. The only thing I know of for affected tubers is to dust them thoroughly with dry brimstone, and keep them from further damp. Rotten claws may be detected by their soft and brown consistency by the moistening process I have spoken of. Healthy claws are white inside. Prevention is better than cure.

I reserve for my last note a deeply important crisis in the culture of the Ranunculus; this is, taking up. No amount of attention to soil or anything else will atone for negligence here. The new tubers strike directly the vigour of the bloom and foliage is past, and every new fibre struck out and afterwards unnaturally checked is weakness to the tuber. It must not only be replaced at some expense, but easily affords a starting point for mildew to lay hold of. The bloom ought to be shaded, for the first heavy rain upon expanded flowers will beat all down, and break many. The cover should be left on till all are taken up, and it will thus keep the ground both cool and dry, and free from the warm stimulants of July rains and sun upon the excitable tubers. I never water my beds artificially, preferring to shade them against very hot sun. But a dry May is always against the Ranunculus, and watering seems to weigh little in their favour when the air is dry and weather rainless.

In Rome I saw a few years since a bed of Ranunculuses that were just opening their buds about the beginning of February. They were double, and some edged flowers among them, but the full quality I could not discern. I thought how grandly this neglected flower might be grown where it could remain to form clumps, only to be moved a moment for rearrangement. Were it in my power this is how I would grow my Ranunculus: I would yearly top-dress the beds, and replant immediately, affording the foliage a glass protection as of a house, freely allowing light and ventilation, and possessing frost-proof powers.

But this is not the place to build glass castles in the air. I have known the florist Ranunculus since my boyhood, and I go on with it in the old way. I have had failures and successes, success surviving the partial shock of failures. Perhaps a chequered experience like this, being natural, is a useful sort of a one to recall.

I am glad to say a word for one of my dear old favourites, and if it will be of help or interest to any fellow cultivator, or if it will lead any young florist or older hand to say "I will make love to the Ranunculus," it would than repay me for a congenial scribble.—F. D. HONNIA, Kirkby Malzeard, Ripon.

## POTATO HUMBUG.

I AM an ill-used member of society. I once bore a respectable name, was well thought of, used to present an open countenance to all comers; but I now begin almost to doubt my identity. Such things are perpetrated either in my name or by members of my family, that were it not for the regard still entertained for me by some of the best members of society, and the ready manner in which I am welcomed at the tables of most of the hotels and restaurants of our great city, I should give myself up entirely to the tender mercies of "W. G. S.," and be contented to be macerated and fungolised until there was none of me left; and the worst of it is that all this while I—(or at least my family are)—am bespattered and bepraised. I am called the "noble tuber," the "indispensable adjunct" to the table of the rich and the cottage of the poor. My rotundity and smoothness of skin form the subjects of encomiums loud and long. My eyes even come in for their share of praise, and were I to believe all that is said of me I should probably "get cheeky" and grow up into a Potato tree. But alas! I recollect that something of the same kind holds good of the horse. He is a "noble animal," people never tire of sounding his praises; and yet it is a well-known fact that horse-dealers, jockeys, ostlers, and racing men in general are not supposed to have the strict sense of honour, or be remarkable for the purity of their language or the innocence of their lives.

When, sir, placed amongst a few others of my fellows at

South Kensington, I, a good honest "Sawnie," looked down the arcade and saw what at first I imagined to be a small section of Tooley Street, and heard certain whispers from those who were visiting the place, I thought "the force of humbug can no further go." Bravo, Yankee Doodle! you are a "smart 'un," and have certainly "wiped the eye" of us poor Britishers. It was a smart notion that, setting us to see how many pounds could be grown from one pound of seed. However, like Shylock's pound of flesh, there is more behind. I wonder whether there is any truth in the statement that along with the offer of the prizes there was a "Bliss-ful" suggestion that a pound of eyes was a pound of Potatoes. But what an absurd humbug it was altogether! An uglier member of my family than one of those exhibited Eureka I have never seen; indeed I rather thought it was an "ugly mug" raised by my friend Mr. Paterson—"Bovina," which had been sent out to Yankeeedom, and then, with a feeling that does them infinite credit, had been rechristened and sent back to us. And then who was to tell whether the pound had been honestly gained and planted? And even if all were "honourable men," what possibly could these, being sent to South Kensington, do in confirmation of this asserted fact? The Fruit Committee of the Society never did a wiser thing than declaring they would have nothing to say to such a barefaced humbug.

As I am on this point I may as well say a few words on Potato shows in general. If they are to serve any good purpose, which I very much doubt, they must be very different to what they are now. I believe that it is no secret that some of the principal prizes at the Potato Show at the Alexandra Palace were gained by people who never cultivated one-quarter of the Potatoes they exhibited, and that even respectable firms were sending in all directions for dishes of Potatoes. There was no rule against doing this, so that there was no dishonesty in the matter. But what purpose can it answer thus to exhibit? Moreover, a Potato Show gives no idea of the value of the sorts exhibited either as to productiveness or quality. It is not true of the Potato that "one may smile and smile, and be a villain;" but one may look well, have a smooth skin and be altogether presentable, and yet have not the slightest claim to be of any use. I could name varieties which are described as fine exhibition kinds, but which are utterly useless for the table. And what have exhibitors done to improve the Potato? Have they suggested better means of culture, taught us anything about the Potato disease, or advanced in any way the "noble tuber"?

And now as to varieties. Here is one of the grand sources of humbug. I look back a few years and I remember, besides myself, some of my excellent friends who then were highly esteemed. There was my dear early companion Myatt's Ash-leaf; Old Lapstone, a sturdy Yorkshire boy; Dalmahoy, who hailed like myself across the border; Victoria, worthy of her name; and a few others. We thought we were decent fellows, but we were told that we might as well hide our heads. A flourish of trumpets came "floating o'er the sea." Enter a host of Yankees—Early Rose, Climax, Prolific, Vermont Beauty, Very Early Vermont, Brownell's Beauty, Eureka, Snowflake; one after the other they came, and with one or two exceptions they have met the fate many of us predicted they would. Early Rose was to beat all early Potatoes out of the field, but I know one case at least where two or three acres were planted and the luckless grower can get no sale for them. Now and then one hears of one which in some place or other has answered, but the general verdict is, "Fit for the pigs." I saw in a contemporary the other day that an "eminent firm" has been dodging the public by letting out at least three old Potatoes under new names, and I doubt not the said firm will find out that other "eminent firms" have been doing the same. One fruitful source of new (?) varieties is that sometimes a Potato grown under special circumstances assumes a different character for a while. It is immediately seized upon by some "eminent" letter-out of "novelties," but when it comes into general cultivation reverts to its original type. Oxfordshire Kidney, Cambridgeshire ditto, Somersetshire ditto, and a host of other names suggest themselves where one Potato does duty under a number of aliases, for all the world reminding one of Woodin or Howard Paul, who appear in twenty different characters in as many minutes.

With regard to those which are really new varieties, such as those raised by that enthusiastic horticulturist Mr. Fenn, I wish one could speak better of them than I find myself able to do. They seem to me sadly to lack flavour. They are

mealy, but they want that genuine Potato flavour which is possessed by such varieties as the Lapstone or by myself; and they are, moreover, so liable to disease that they can never come into general use. Rector of Woodstock is one of the very first to be smitten by the disease, and generally suffers more than any other early variety. Onwards is a ball of flour, and in truth tastes very like it.

I am not, I hope, conceited, although, like most of my countrymen, I do not like to be underrated; but I very much question whether amongst round Potatoes—(I say nothing of kidneys)—there has anything come out, either old or new, in the last few years that can "take the shine" out of your old friend—THE DUNBAR REGENT.

### GROS COLMAN GRAPE.

"EX-EXHIBITOR" asks for experiences of Gros Colman Grape; I give mine. Some years ago I planted a Gros Colman Vine which was sent to me by mistake for another variety suited to a cool vinery. It grew and fruited freely, but the fruit was quite worthless, as it never ripened. Still I let it remain; but this year I gave it plenty of heat, and was rewarded by an excellent crop of well-ripened Grapes, which came in when all my others were gone, and have kept well up to the present time. I am confident they would hang much longer, only that I was obliged to shut off heat for the sake of bedding plants, which I wished to keep at rest.

During the summer I gave the Vine a good deal of liquid manure, as its large berries require liberal feeding to swell them properly. I also thinned the berries well, and did not allow much more than half the bunches to remain. Everyone who has tasted it pronounced it all that could be desired in flavour. I may add, that though I gave plenty of heat, I gave also abundant ventilation. I consider Gros Colman a first-rate late Grape for a well-heated vinery, and worthless under other conditions.

Is not "EX-EXHIBITOR" in error in saying that Mr. Rivers describes Gros Colman as ripening its fruit in a cool vinery? In his catalogue for this year he gives a very good description of it, and says it requires heat.—FREDERICK TYMONS, Cloghan, County Dublin.

["EX-EXHIBITOR" may have referred to the time at which he planted his Vine. In Mr. Rivers's catalogue for 1870 Gros Colman is marked "C V." What is the experience of others on the quality and cultural requirements of this fine-looking Grape?—EDS.]

### NEW GLADIOLI.

THERE is evidence that our English growers are endeavouring to turn the tables on the French raisers as they have done in the matter of Roses; for while M. Souchet, or rather his successors Messrs. Soullard & Brasselot, advertise a dozen, Mr. Kelway of Langport sends out eighteen new varieties, some of them double—nay, treble of the price of the French varieties; and in a catalogue sent to me by Messrs. Robertson and Galloway I find, besides the French and Langport varieties, a number of others raised by Mr. Sampson of Yeovil marked at the same high figures, besides some raised by Messrs. Cunningham, Codling, and others: and as I am frequently asked what is my opinion of the novelties, it may suffice for my many correspondents if I give these few notes. Of the foreigners I know nothing from personal observation, having been prevented from paying my annual visit to Paris and Fontainebleau this year. I have neither seen anything nor heard much of them. A friend has, however, told me that the following may be relied upon as really valuable varieties—Fiammetta, Léandre, Phoenix, and Titania, and as I find them amongst the highest-priced sorts of M. Souchet's lists I have little doubt that they will prove to be as reported to me. The descriptions given of them, thoroughly French and characteristic, are as follow:—

*Fiammetta*.—Splendid spike of perfect flowers; white ground glazed with tender rose, largely and richly blazed bright carmine; large yellow spots, striated carmine.

*Léandre*.—Extra large flower; very long and splendid spike, slightly tinted carmine; very large spots, pure white, with a white line on each division.

*Phoenix*.—Large flowers, cherry rose, white, pure ground edged light cherry rose, blazed darker.

*Titania*.—Very long and large spike; flesh salmon colour flamed cherry on white ground.

I confess that these descriptions puzzle me, and that I have not the slightest notion what they will be like. Besides these there are *Amaranth*, a lilac rose; *Camille*, tender lilac; *Christophe Colomb*, carmine rose; *Columbine*, cream colour; *Esther*, white flamed with rose; *Hecla*, orange red; *Miriam*, white; *Niobe*, tender rose; and *Rosita*, carmine rose.

I now come to the Langport seedlings. No one who has seen Mr. Kelway's exhibits for the last few years can doubt the success which has attended him as a raiser; but one may be permitted, with all that, to question such statements as that those to be let out now are in advance of any in commerce. They are certainly as far as price is concerned; for while the highest-priced one of *Souchet's* is about 11s. 6d., I find *Agrius* marked at 80s., two more at a pound, and seven at 15s. Those which I have seen, and indeed in some cases helped to describe, are the following:—

*Agrius*.—Salmon pink, flaked at the edges with vermillion, with a creamy yellow eye. This flower obtained a first-class certificate at the Metropolitan Floral Society's Show in August last, and is unquestionably a grand flower of great substance.

*Archelaus*.—White flaked with rose, with purple stripes on yellow ground.

*Gwendoline*.—Flesh, with a rose stripe on lower petals. This flower was exhibited at the Crystal Palace, and is certainly very remarkable for its colouring.

*Lord Howard*.—Orange crimson; lower petals white.

*Lord Petre*.—Orange crimson; lower petals carmine. This is another of the Crystal Palace flowers, and is also a fine variety.

The others are flowers which have been exhibited at provincial shows, and I cannot speak of them from personal acquaintance, although I have a faint recollection of *Agnes Mary* at Taunton as a very curious flower, white marbled with slate, with a violet stripe on the lower petal.

Messrs. Robertson & Galloway of Glasgow gave us a taste of their quality when they entered the lists at South Kensington and plucked the crown from Mr. Kelway. I have a faint recollection that some years ago, when our friend Mr. Dix inaugurated a grand exhibition of *Gladioli* at South Kensington, the same firm sent up a very fine stand of flowers, but that they were too late for entering. The flowers that they exhibited at South Kensington were all, or nearly all, French flowers. Although their list comprises, as I have said, many valuable varieties of English growth they announce but one new variety, and that not raised by themselves but by Mr. Codling at Morpeth. It is described thus: "*Marquis of Lothian*.—Rose colour flushed with mauve; the lower segments creamy-coloured towards the base, with crimson flame. Resembling *Lacépède* in hue, but is superior to it in size, form, and colour."

There can be no doubt that, despite its most trying character, the *Gladiolus* is a thoroughly popular flower, and it may be that the very difficulties connected with its culture make it the more valued by those who are any way successful with it—like the *Auricula*, which no one ever likes to abandon; but the *Auricula* is not subject to the same terrible malady which so often disappoints the hope of the *Gladiolus*-grower.—D., Deal.

## PROPAGATING *FICUS ELASTICA* FROM BUDS

No plant has become more popular than this. It is useful either for subtropical gardening or for indoor decorative purposes, for which it is better adapted than any other plant that I am acquainted with, as it will stand the heat and gas of a room for a lengthened period without being injured—in fact, the finest plant I ever saw had been growing in a room for six years.

The present time is the best for propagating this plant, either by shoots taken off with a heel or by eyes. When it is propagated by eyes they should be taken with a leaf attached to each, and be placed in silver sand to keep them from bleeding. Insert them in small pots well drained, in a mixture of peat and cocoa-nut fibre, and plunge in a strong bottom heat of 90°, with a little sand under each cutting. If they are not placed in a strong bottom heat the eyes will not break. When the eyes have rooted and commenced growing they should be repotted into 48-sized pots, in equal parts of turfy loam and peat, with sufficient sand to keep the soil open. The plants should be placed in a temperature of about 70°, and be syringed frequently; occasionally sponging the foliage is also highly beneficial. The plants should never be allowed to

become potbound until they have grown to their allotted size, when they will be greatly benefited by liberal supplies of manure water. During their growing season they should never be allowed to become dry at the roots, as dryness causes the leaves to turn yellow and spoils the beauty of the plants.

Shoots taken off with a heel will make plants much quicker than raising them from eyes; and it is the safest plan, for if strong bottom heat is not afforded, the eyes, as before mentioned, will not break into growth. When only a few plants of rapid growth are required I advise that they be raised from cuttings, but when a great number of small plants are required, which is not unfrequently the case now *Indiarubber* Plants are fashionable, the mode of raising them from eyes must be resorted to.

*Ficus elastica* is a native of the East Indies, and was introduced in 1815. It was formerly grown in stoves, and was merely preserved as a curiosity; it may, however, be kept safely in a winter temperature of 45°. It is one of the most appropriate and ornamental of window plants, and is invaluable for many other purposes of decoration. Plants are now in great demand, and are being rapidly increased by the above modes in most nurseries, and they have a large sale in Covent Garden Market.—A. Y.

## EFFECT OF SEASONS ON PEARS.

THE last two summers have been so totally different in character that a good opportunity has been afforded of noting their effects on the different varieties of Pears. The dry summer found us with fruit clean-skinned, beautifully coloured, and high-flavoured; but small fruit which ripened early rotted at the core sooner than usual. Each season should furnish us with a greater knowledge of fruit, and I think we generally find that Nature offers us a very excellent lesson in the way she carries out her handiwork. There is in nature a compensating method of procedure that we should not hesitate to adopt. I believe we seldom find in one season all those necessary ingredients to build up a really first-class fruit. We obtain one quality at the expense of another; so that this season, being a wet one, has found us with larger fruit but not so highly flavoured, skin rough and deficient in colour, most kinds being later in ripening coming in very irregularly and keeping indifferently.

There are some exceptions to this rule, no doubt, and we find some varieties do well in the one season and really worthless in the other. This I have found with two stewing Pears, and I should be glad to hear from anyone who can give an explanation why the *Uvedale's St. Germain* should give us such fine clean fruit last summer (1874), and the *Catillac* so small and worthless, and now, on the other hand, this summer for the character of each to turn quite round. The *Catillac* I never saw better, the *St. Germain* I never saw worse—quite worthless indeed, being not even sound, but cracked, rusted, and very small. The difference is very remarkable, and it seems a safe practice to have the two varieties; we are then provided for either wet or dry seasons. I may say the trees are both standards and growing side by side.—J. TAYLOR, *Hardwicke Grange*.

## HEATING A VINERY FROM THE KITCHEN BOILER.

MANY are the inquiries as to heating a glass structure adjoining the residence by a pipe connection with the boiler of the kitchen fire. To this end there have been many trials, many failures, and some successes. A success was noted by Mr. Taylor on page 527; another, and a very complete one, we now place on record. The accompanying ground plan and section has been taken and forwarded to us by Mr. J. F. Pearson, of Branston, near Lincoln. The vinery is attached to Branston Villa, the property and residence of Mr. T. Lovelee, a practical builder. The mode of heating was devised by himself. In this vinery, and another of much larger dimensions, Mr. Lovelee has, during the past few years, grown some of the finest Grapes in Lincolnshire. He has, during a successful career, invested in house property in town and country; but no buildings have proved so lucrative as his vineries. These he manages himself as a source of recreation; but he is ever ready to acknowledge the value of the advice and assistance of our correspondent Mr. J. Wright, who was gardener to the Hon. A. Leslie Melville when Mr. Lovelee commenced his preparations for Grape-growing.

Theinery heated from the kitchen boiler is a house about 10 feet having a north-east aspect, the long roof of 18 feet 18 feet square, having a half-span roof, the short roof of about length of rafter facing the south-west; the south upright end

GROUND PLAN-

Fig. 115.

is also of glass. The exposure is thus considerable. The produces heavy crops of fruit which ripen perfectly. For the first few years after planting the Vines the interior of the house was planted with early Potatoes, and excellent crops

were produced, which paid interest on the outlay until the Vines were in profit. The house now contains a plant stage for wintering Geraniums.

The heating at first was not a success. The kitchen boiler was not large enough, and another square boiler was connected to it. The flow and return pipes were inserted at the end of this boiler, one beneath the other, and necessarily close together. The pipes were also taken round the house level with the boiler, and the feed pipe entered the top of the boiler. That was not satisfactory. The pipes were taken out and the end of the boiler plated over, the flow pipe then being placed at the top and the return pipe at the bottom of the boiler, the feed being also conducted into the return pipe. The pipes (4-inch) round the house were also raised, the flow gradually rising to the highest point near the door (where an air pipe was inserted), then doubling under was conducted beneath it to the boiler. The circulation was then complete, but the fire was not "sharp enough" to heat the double boiler. A separate fire was next built up in the inside of the vinery and taken into the flue of the bedroom. The fire, before entering this flue, traverses entirely round the boiler. The heating power of the fire is now complete, and indeed, but for the damper in the vertical flue, the draught would, to use the owner's words, "tear all the fire out of the grate." The damper is the heat-governor, and is drawn when heat is required in the pipes. Not many boilers of the most approved and modern construction will do their work quicker and better than this simple homely contrivance.

The raising of the pipes, the flow and return entering the boiler as widely apart as possible, the exposure of the utmost boiler surface to the fire, and the separate tall vertical flue to afford draught, are the elements which have ensured success, a success which will follow all similar efforts if correctly carried out on the same principle, which is so clearly shown in the engraving.

But besides the arrangements there is another condition to be attended to—the fire must be there, and in severe weather early in the morning. When failures in heating occur it is not always the apparatus that is so much in fault as the fire-maker. Those who are the most successful in providing a proper temperature in glass structures are those who "stir the fire" early in the morning.

### NEW ZEALAND.

We append a part of a letter from one of the members of the Maidstone Gardeners' Mutual Improvement Society to a fellow member, giving a few particulars of that important colony and its climate and production, from which it will be seen that there are many features of attraction about it which may not be known to all.—A CORRESPONDENT.

"The weather commenced in the beginning of September to be very warm with any quantity of rain. It continues very warm at present (May 31st), with sufficient rain to cause vegetables to grow at a rapid rate. Winter here appears to be made up chiefly of rain. I have not any recollection of seeing ice last winter, but on two mornings only; it then disappeared in a short time—something like a very sharp May frost that I have seen in England. It is very cold at the extreme south of the country. I was at a place 150 miles farther north than this at the end of October, which is equal to April in England.

"As affording some idea of what the climate is in places, I may note that we have scarlet Geraniums 6 feet high with any quantity of flower on them, Pelargoniums 8 or 4 feet. New Potatoes and Green Peas are plentiful, and we have some of the finest Asparagus I ever saw; Peach trees about 14 or 15 feet high loaded with fruit about half grown; white Arum just now blooming for the second time in the open borders. A plant of *Oleander* (*Glory Pea*) is about 7 feet high in the open border, and is now showing for thousands of flowers.

"The Ferns alone would charm you. Only think, when one stands looking at one of those magnificent tree Ferns from 12 to 20 feet high, and then look around in that small space and find a rich variety of small Ferns. There is a stump of an old tree Fern in the garden here measuring about 5 feet 6 in girth.—A. GIBB."

### NOTES AND GLEANINGS.

PROFESSOR KERNER of Innsbrück has published an interesting pamphlet on the HYBRID PRIMULACEÆ OF THE ALPS. Of these he enumerates no less than twenty-five belonging to the genus *Primula*, four to *Androsace*, and two to *Soldanella*; some of which have been treated as independent species, as that between *P. subcaerulea* and *officinalis* under the name *P. brevistyla*, DC., and that between *P. superauriculata* and *hirsuta* under that of *P. pubescens*, Jacq. By far the majority (twenty) of the *Primula* hybrids belong to a single section, *Auriculastrum*, the remainder to *Primulastrum*. Of "derivative hybrids"—that is, those resulting from the crossing of a

hybrid with one of its parent forms—he knows only one or two certain instances.

—SLEEPER'S DWARF PEACH TREE originated and is grown by Mr. Sleeper of the Oxford Nursery in Indiana, U.S. It stood without protection the severe winters of 1872 and 1873, with the mercury at 28° below zero, and bore the fourth crop. It appears, therefore, to be very hardy. Its habit is quite dwarf, being but 8 feet high at eight years old. The size of the fruit is medium to large, freestone, greenish white, and a little crimson in the sun, the flesh being juicy, sweet, and rich. Being dwarf, winter protection would be easy.—(*Indiana Farmer*.)

—EUCALYPTUS GLOBULUS has had its share of attention in India, and without considering the question of the truth or otherwise of its reputed value, it is proved that although it grows quickly and with vigour on the Neilgherries and Khasia hills at 5000 to 8000 feet above the sea, it cannot be induced to live even for a year or two in the hot plains of India. Dr. King's description of the fine old Banyan tree, "one of the greatest curiosities and ornaments of the place," will, we are sure, be read with interest. He says: "Although considerably damaged by the cyclone of 1864, which carried away two of its largest arms, this fine tree continues to grow vigorously. It now covers an area of ground 800 feet in circumference; its trunk girths 51 feet, and from its branches no fewer than 170 aerial roots are sent down to the ground, some of them being more than 10 feet in circumference. This fine old tree supports quite a colony of Orchids, Ferns, and creeping plants of about twenty distinct species, and gives shelter to innumerable birds. Its exact age is not known, but, considering how rapidly Banyans grow, it probably does not much exceed that of the garden, and is therefore less than a century."—(*Nature*.)

—At a recent meeting of the Californian Academy of Natural Sciences, Dr. Kellogg said he had just returned from under the shadow of the finest evergreens ever grown. He hoped the secretary would record the fact that there were in California GOLDEN CHESTNUT TREES (*Castanea chrysophylla*) from 100 to 200 feet high, 4 to 6 feet in diameter, and with an unbranched trunk of from 50 to 70 feet.

—To wherever Englishmen emigrate they endeavour to render their adopted home like "the old country." We remember in India the care taken to make an Apple tree live; and the last gift handed up to an emigrant from a boat by the ship's side was a lark confined in an old stocking. We honour these clings of the heart, they testify that they have loved home well. We have just received another such testimony as a record of another effort to make a settlement at the antipodes like England. It is a well-printed little pamphlet entitled "Schedule of Prizes—GRAND CHRISTMAS EXHIBITION of pot plants, vegetables, poultry, &c." To be held at Hokitika, New Zealand, on December 27th and 28th. The prizes are not large, but then the entrance fee is only sixpence. There is but one native production encouraged, one class being for "native pigeons," first prize 10s., second 5s. There is the following advertisement appended which may aid some of our readers:—"The undersigned makes named collections of New Zealand Ferns for exportation to all parts of the world. Collections named and fronds collected for drying.—WALTER TIPLER, Kanieri, Westland, New Zealand."

### IVY FOR CHURCH DECORATION.

FREQUENTLY this evergreen is used in bunches in a flowering state, but let me say how effective it is in churches when used in its natural clinging manner. For some years I have been connected with a church which has been elaborately, yet tastefully, decorated by willing helpers, who have rivalled each other in their treatment of the several parts of the edifice. All was perfect except the windows, and now these are made so (the congregation being the judges) by the use of Ivy alone.

The small English variety is used—the sort that clings to stems of trees in woods. Sprays of these are obtained, their bases placed near the glass, and their points at an upward yet irregular angle are trained inwards on the walled recesses of the windows; a spray is occasionally taken across the glass and made to climb up and around the mullions. When tastefully—not formally—done the effect is perfect, being light, airy, and so natural that it appears to be growing in its own wild manner, and has found its way from the outside to the inside of the church.

The runners may be glued, tacked, or tied on the walls as is

most suitable and convenient. They are perfectly flat when taken from the stems of trees, and will fit anywhere.—*CHARICUS.*

### THE OPHIOGLOSSUMS.

THIS genus of plants is closely allied to the Ferns, and many of the species have claims to cultivation. They are a class of plants quite distinct in appearance, and, like the *Platyceriums*, are quaintly ornamental. The family has a wide geographical range, one species being found in British meadows and others

a great depth of soil, but will luxuriate in a rough open composition of sphagnum, turfy peat, and charcoal, if a place is afforded it in a well-heated structure, and a copious supply of water is given in the growing season. This species when well grown is a distinct and ornamental plant, and one that is well worthy of all the care that can be bestowed in its cultivation. Plants may be increased by divisions of the root or by seeds, but in either case the process is a slow one, and for a supply of these plants we must rely mainly on importations. The Portuguese species *O. lusitanicum*, and the British species *O. vulgare*, are the most common, and have a place in most large collections of plants.—*W. J. B.*

### CONCRETING VINE BORDERS—WATERING • POTTED PLANTS—FRAGRANT ROSES.

LET me thank "A NORTHERN GARDENER" very much, and congratulate him also on his very able article with regard to concreting Vine borders. I thoroughly agree with and can endorse all he says, as both theory and practice will bear him out, and I can recommend all who are making new or renovating old borders to read the article over again. I am sure more harm is done from keeping borders too dry than from having them too wet. Not long ago a friend of mine changed his gardener, and when I was staying with him in the October following he complained of his Grapes shanking and being much worse than they had ever been before. On inquiry I found the new gardener had covered the Vine borders during the winter and up to May with rolls of asphalted felt, which were so arranged as to throw all the water off the beds. The Vines have never yet properly recovered the treatment, as a dry season followed, and I do not think they ever will.

There is another question, and that is also a most important one, I should like again to have ventilated in your columns, and that is with regard to watering plants in pots in stoves and greenhouses during the winter, when they are supposed to be in a state of rest. I see constantly advice given to give some stove plants 55° to 60° as minimum temperature, and yet to withhold water. Now, though plants may not be in active growth, yet all plants that retain their foliage, such as *Allamandas*, *Bougainvilleas*, *Passifloras*, &c., must suffer very much if the roots are kept too dry; besides, too, as a general rule, far too high a temperature is recommended for plants at rest. We should remember that plants in their natural state generally have their roots more moist in winter when in a state of rest than any other time; take, for instance, Vines in the vineyards of Lombardy or the South of France, or in the champagne district, and the same law applies, almost equally, even in the more tropical districts.

The query arises whether the roots of plants are really ever in a state of rest, and whether, even in deciduous plants in the colder regions, there is not a circulation of sap sufficient to keep bark and buds healthy and plump. I feel confident, from my own experience, that stove and greenhouse plants often suffer in winter from being kept too dry, so that the fine spongioles of the roots are killed, though of course they may equally suffer if a pot is allowed to be waterlogged; but where the temperature of a house is kept up to 55° by fire heat, plants in pots are much more likely to suffer from dryness than moisture, and many of our stove and greenhouse plants will stand far more cold than is generally supposed. I have seen several kinds of Orchids frozen without injury; again, I have seen *Calceolarias* and *Cinerarias* and *Verbenas* kept dust-dry, and have known complaints made at the same time of their damping-off, when all that was wanted was a plentiful supply from the watering-pot. I should consequently like to draw the attention of your correspondents to these points.

FRAGRANT ROSES.—I quite agree with Mr. Hinton that I was surprised to see François Lacharme omitted in the list of scented Roses. I did not take my part in the election either of new sorts or of Roses for scent, because I had not given sufficient trial in my own garden of the newer sorts, and I thought the question of scent so merely a matter of individual taste that no very definite good could come of it; and so I think it has proved, considering more than 150 Roses were named for twenty-five best and most highly scented. Very likely François Lacharme was omitted because it is in most soils a bad grower, but the question of growth was no element in the case. My own feeling is, Grow a certain number of Tea-scented and other Roses for the sake of their buds and their scent, but never discard a fine Rose even if the scent be nil. Is there,

Fig. 116.—*Ophioglossum palmatum.*

in New Holland, Portugal, Japan, and the West Indies. The genus is named from *ophis*, a serpent, and *glossa*, a tongue, and hence the name of Adder's-tongue, which is the popular name of the familiar English species. One of the most curious of the family is *O. pendulum*, which is a native of Madagascar, where it is found growing on forest trees, its fronds hanging from the branches to a length of several feet. It is often found growing with *Platycerium grande*, and requires much the same mode of cultivation as that quaint plant. It is at home on the rocks of the tropical fernery, and will grow freely in a spongy mass of peaty soil.

*O. palmatum* is one of the best of the species. It is somewhat rare, yet is not difficult to cultivate. It does not require

again, the slightest difference between the scent of Abel Grand and Bessie Johnson? I certainly cannot trace it, and why should Bessie Johnson take precedence of Abel Grand, from which it is only a light-coloured sport?

**SMALL BIRDS IN FRANCE.**—I was called to task with regard to my statement as to the absence of small birds in France. There may be regulations as to the destruction of small birds in Switzerland, but it certainly has not succeeded in increasing the number across the border. Nor can I say much for bird life in the woods alongside the Lake of Lucerne, as in the three or four days I was in that neighbourhood I hardly saw one, and with the exception of a few pert sparrows in the Jardins de Tuileries and Luxembourg I hardly saw a bird for the five weeks I was abroad. An occasional magpie or half a dozen rooks to be seen out of the railway carriage on one or two rare occasions was all that we ever saw. Yes; I must make one exception. I found a nest of young nightingales at Bellagio, and had the pleasure of seeing the old birds go and feed them, while they occasionally rested from their labours to give one of their sweet and thrilling songs.—C. P. PEACHE.

### THE DECORATION OF CHURCHES AND PUBLIC ROOMS WITH EVERGREENS.

AMONGST the many duties of the gardener sometimes are included the Christmas decoration of the church; not but that the clergyman and most likely a committee of ladies do most of the designing and a great deal of the execution of the work, still there is always something requiring the aid of hands more accustomed to rougher employment—a ladder to lift and mount here and there, and the skill to put in position. Letters, however carefully formed, look bad if not fixed with due precision one to another, and the fixing is by no means easy where possibly a mandate has gone forth that nails must not be used. How many times this law is broken I will not attempt to say, but may remark that it is not always an easy task to fix anything very heavy when perched on the top of a ladder, notwithstanding the multitude of advisers below. However, those having the work in hand are usually equal to the task, and the result is generally satisfactory. Not but that there is considerable diversity in the mode by which such works are done, and not a little emulation often exists amongst the decorators who dress out the rival churches in a town; and now and then we should be inclined to think that decoration, so called, is carried a step too far, and the effect produced is the reverse to what ought to predominate in such a place. There ought certainly to be some difference between the decoration of a place of worship and that of a ball-room, apart from the mottoes.

I will try to show that a very good display may be made with evergreens alone, and hope that by a liberal use of them to satisfy the demands of those who look forward to the decoration of their parish church as one of the pleasantest occupations they engage in.

Taking it for granted that whatever additional substances are used for the embellishment evergreens form the principal, to these we will more especially devote our attention. And for church decoration long-established usage has given the most prominent place to the Holly—in fact without Holly it would be difficult to conceive it was really Christmas; therefore in all places where it can be worked-in Holly is used, and with a little care its rather awkwardness to fit into the desired place is overcome, and wreaths as well as lettering is performed with Holly tolerably well; and we have seen the toothed work that very often surmounts the moulded screen bristling with Holly, which by a little management was made to stand in upright sprigs by being secured in their place by pieces of cork voting as wedges in the recesses of the notched work, and no mark nor damage done to anything by the operation. It is, in fact, the knack of hitting on expedients to fit the decoration in its place that is most needed in works of this kind, as we expect the stringent order against nails to be duly regarded. But advertising again to the Holly, we confess to a dislike to see it mutilated to the extent it is often done, and would rather see it oftener in its normal condition with its clusters of berries surmounted by a few inches of stem having leaves on only. That the latter partly hide the berries is perfectly true, but they look more natural; and in most cases where both they and the foliage are permitted at all let them appear as grown. A very slight wreath of variegated Holly for some especial purpose might be allowed to have a tuft of berries worked into

it that had been denuded of its foliage, but the more seldom the better. A branch of Holly against a wall looks better than when the same is worked into an artificial wreath or festoon, for it is rather unmanageable; and although its leaves may be tacked on to a piece of lath, and designs as well as lettering formed of it, and its shining leaves richly ornamented with prickles give it decided preference to everything else for this work, it is less convenient to deal with when its foliage and its berries are wanted to be worked into small wreaths, or for small work of any kind where the leaves are not stripped off; and excepting at Christmas it seems not to enter so largely into decorative purposes as other evergreens, and even then churches would seem the places where it exercises its greatest sway; and probably no other evergreen will stand so long or bear the heat and dust of a dwelling-room at Christmas time so well as this highly popular evergreen, and certainly none is so extensively used.

I may be allowed to diverge a little by way of warning as to its disposal, after doing the honours of Christmas. A few years ago some sprigs of Holly that had done service over the mantelpiece, &c., of a farmhouse near here were thrown into the fire one evening, and blazing up were carried up the chimney and across a road, and landing on a thatched roof set fire to it, and much damage was done, a high wind blowing at the time fanned the flames; it would therefore be advisable to be careful with the dried Holly leaves. Let us, however, take a surer and see what other plants furnish us with the means of making our public rooms, as well as churches, ornamental at this season.

Next to the Holly for church decoration a variety of evergreens are often met with worked-in more or less into the design. Ivy, which as a national plant claiming equal importance with the Holly, is largely used, as is also the Yew, a tree equally sacred; in fact, I much question whether any three shrubs or trees of foreign extraction can equal these three for appearance and effect in their different positions; but we will treat with them now as being equally available for other decorations as well as that of the church, the Ivy especially being a favourite in every way, and wreaths or festoons formed of it look, perhaps, better than anything else when it is so placed that all sides are visible to the eye; the under side of the Ivy leaf being nearly as pretty as the upper side, which is not the case with many evergreens. We usually prefer the short bushy twigs from old plants to make festoons, and if loaded with berries so much the better. Our mode of making festoons of this, as well as other kinds of evergreens, is to have a quantity of twigs prepared, and a temporary table or bench formed; they are placed upon it, when the operator takes a piece of string, seldom or never thicker than the blacklead which forms the writing part of a pencil, and a loop being made at one end is fixed to a nail or hook at the end of the table, and with not more than 4 or 5 feet of string to work with. One or two twigs are taken in the left hand, and a sort of a hitch knot is made with the string near the point of the twig, and one or two more twigs being added near the base or butt-end of the twigs, a similar hitch knot is made there with the same string, the operator walking backwards as he proceeds, and having his right hand to the table where his supply of evergreens is. The process of forming a great length of festooning available for hanging up anywhere is a much quicker one than many suspect, although as will be seen by the above that each twig has two ties, one at each end, and the whole being in fact what may be called heads to tails. Of course some little care is necessary not to confine any leaves with the string if possible, and a few inches of the tip ends of each shoot should extend beyond the tie, so as to look less fettered.

I should not like to guess how many hundreds of yards of festooning of this kind our men have at various times prepared, but it would be a great many miles; of course not of Ivy alone, but of other evergreens as well—Laurustinus, Sweet Bay, and Alaternus being all quicker and faster made up than Ivy, and all looking well. While one of the neatest of all is Box, which is capable of being made up much lighter than most other sprays, unless it be Cypress or Yew; but most evergreens are available for the purpose. The best, however, being those having leaves not too large; for that reason the Corsican Laurel is not so good as many evergreens, and the Portugal Laurel, though looking very well at first, is not the best to stand many days. Neither is the Laurustinus so good as Box, but the Phillyrea does very well. But it is not always that a selection can be made, and now and then the result of a trial is not satisfactory; the Evergreen Oak being marred by the white on

the under side of the leaf, and a similar fault was once found with some Rosemary that was worked into the same purpose. I have never tried Butcher's Broom, its harshness seems against it; but I have seen a very neat wreath of Myrtle, which, however, cannot always be had in quantity. *Cupressus Lambertiana* makes a very nice wreath, and so does most of the others that do not present the flattened form of the *Arbor-Vitæ* class. Pinuses sometimes are used, but they are not generally admired; and all the Silver Fir section, like the common Laurel, look best when a good large branch is fixed up without mutilation. But there is ample variety of material to work into the purpose stated.

In mentioning the above as being capable of being made to any extent, I may add that they unite together very well by tying the string that forms them together, and the joint is not perceived. I may also add that they will carry about anywhere without any material injury, which is an important matter when they have to be sent to a distance. A very little tack will suffice to loop them up anywhere almost, while a room may be crossed and recrossed as many times as it is thought necessary if there be a central fastening by which they can be attached to the ceiling, as a hanging gaslight or chandelier; and should the burners be too close to the evergreens by being underneath them, it is better to have a piece of naked wire to fasten their ends to rather than run any risk of their igniting; but we have seen the wreaths remain all right within about 4 feet of the burners without taking any harm. Still it is better to err on the safe side, and a piece of wire fastened to the stem of the gas burner or the chain of the chandelier may extend so far as to reach beyond the action of the flame, and all will be safe. I may further add that it is not unusual to ornament these wreaths with paper rosettes, spikes of flowers, or anything that may be desired. A very good effect is produced by sticking-in shoots of the common Privet when loaded with its black shining fruit; while, perhaps, a more pretty effect is produced when berried Ivy is used by taking the trouble to dip the berries in a sort of batter made of plaster of Paris and water. It dries and hardens in a minute, and ought to be done before the festoon is made, taking, however, a little more care than is otherwise done that it does not get knocked off; but if it be well done it will bear a good deal of hardship, and is very showy, puzzling many what it really is, the snowy whiteness contrasting strongly with the glossy green leaves. Such wreaths may be made of such a variety of material that it is not unlikely but I may have omitted several really useful things; but one I would not like to pass by, and that is of dead foliage, and here the Oak comes out best of anything; and where twigs well clothed with old leaves can be had they may be made to form an important feature in an arrangement. Other dead leaves may also be tried, but I have not seen any that I like so well as the Oak; and I may further add that I have been disappointed in the effect produced by a festoon of *Olinaria maritima*, its leaves so soon fell and had a wretched look; but I daresay some of the variegated *Eunonymus* would be better; but on this head, perhaps, enough has been said.

Besides the above way of making a continuous wreath or string of evergreens any length that may be required, there is another mode equally quick; it takes fewer evergreens, and many affirm it looks better. The plan is this:—Cut the twigs into equal lengths, say 6 or 8 inches, and having the string fixed at one end as in the former case, the twigs are merely tied crossways by a knot fastened to them in the middle, usually two twigs being tied together, with a head or point each way; and at the distance of about 2 inches, either more or less as the case may be, two more are fastened in like manner, and so on to any length, the whole of the shoots being crossways to the string. Generally a mixture of evergreens looks better done this way than when only one kind is used, and some like the plan better than the one "heads to tails" previously described; but when it has to be sent to a distance it is liable to get entangled, unless it be wound round and round something like a very wide board or frame, when it may be undone and hung up in its place. It is very light, and in many places is doubtless better than the heavier one, but both may be used together with advantage, and then the comparison may be made, which it is not easy to give an opinion on without seeing them. Of course in the making of such wreaths great care is necessary not to entangle any of the leaves. I may mention here, that neither in this nor in the other mode of making such ropes of evergreens is an extra string wanted. Beginners sometimes start with one, but if the

festooning be hung up by one end the chances are the evergreens will all slip down to the bottom, so that even when an extraordinary heavy wreath is required it is best to have the string in proportionate strength, and only use one. In a lofty room, or in the open air, where a heavy massive wreath is wanted, say of common Laurel or Oak branches, if it has to be hung, let the cord which suspends them be also the one that secures them together.

Of the mode by which such festooning may be used in a room, the taste of those having the duty of hanging them up will be called into operation, and very little or no damage need be done by such light-made articles as those described. Where there is a moulding we have seen them merely suspended on some part that projects upward, or anywhere where a little hold can be had, as it is only the matter of a few ounces. It is easy to judge that almost anything will bear that. Sometimes it happens when there is nothing at the particular place to attach the wreath to, a little bit of stick may be introduced between two lateral projections sufficiently light to bear the little weight required, or we have sometimes known a common pin forced in where wanted do all that was necessary; but where there is a wooden cornice it often happens that a small tent hook may be inserted in some recess of the moulding where it will leave no mark when taken out. As a wreath of the kind alluded to may be made to surround the frame of the mantelpiece looking-glass, a pin or two keeping it in its place if the moulding in the frame be not sufficient. In a similar way wreaths may hang from each cornice to within about 5 feet of the ground, when, as has been before observed, they may be made to cross and recross the room diagonally or at right angles in any manner that may be required. We once had a rather large public room to decorate, lighted by seven gas burners or chandeliers, hanging in a row from the centre of the ceiling, which was too high to be reached from the floor; but there being access to the roof above, and there being openings where the gas pipe descended, a cord was lowered, and from each of the same places a set of four wreaths was drawn up, which were attached to places at the top of the walls at a sufficient angle from whence they started, so that by crossing each other the large plain roof was in a manner intersected by the wreathing, so as to form a series of diamond shapes; while from the places on the walls where these were secured to, loops of the same were carried round; sometimes a double row of the latter has been worked out, for the arrangement may be varied in many ways.

Apart from the hanging festooning above alluded to, much the same sort of a wreath may be made by tying the evergreens on to a wire bent in some fanciful form; and where the room is too low to allow the evergreen rope as we may call it to be suspended from the ceiling, a very good effect may be produced by preparing a number of wire scrolls to stretch a little way across the ceiling, and, in fact, to touch it, somewhat in the form of cantalivers. These will, however, require to be tied rather securely to the cornice, or the top of the wall where the cornice usually is, one tie being generally sufficient. Usually ordinary fencing wire will be stout enough for this, and the lighter it is the better if it will bear the dressing, which I need hardly say ought to be light also, yet enough to hide the wire. Sometimes a sort of double scroll can be fixed to the opening from whence the chandelier is suspended, and the scrollwork from it almost meet that from the sides. This is much lighter than where the festoon hangs, and is better for a room deficient in height. We have sometimes used wire of a slender kind, plaiting it double or more when strength was wanted, and terminating single at the extremity where lightness was required. Wire, in fact, is exceedingly pliable, and to the church decorator is an all-important agent, its only drawback being that it adds so much to the weight of the ornament when fastenings of the most slender kind only are allowed.

As we have elsewhere said that wherever possible and practicable a branch of an Oak or common Laurel, and several others look better in their entire condition than when cut into fragments to work-up into the form described, and a very good effect is often produced by a number of branches of common Laurel fastened on to the cornice of a room one piece after another, partly against the ceiling and part down the sides; but this can only be done in the room and with suitable fastenings; but we have known these nailed on to a narrow board like those used by slaters, which if coloured green do not show much, and their lengths can be fixed up fast enough.

In like manner we have sometimes used a bit of board not larger than the opened hand, on which neat little flat branches of Laurel or other evergreens can be nailed on, jointing in all directions, and perhaps the junction in the centre can be concealed with some rosette or other becoming ornament. Such a mass of evergreens can be hung in the centre of any large space of naked wall, as a string from the cornice would hardly be noticed, and it is quickly put up.

Another way of preparing a small star for any particular place is to procure large flat leaves of the Portugal Laurel and sew them on to a piece of thick paper or cardboard star fashion, the points of the leaves all projecting outwards and much beyond the paper to which they are sewn. Of course this is lady's work, and a little practice is wanted to do it neatly; but such stars are very useful in this—a small thread will suffice to hang them up against a wall. Neither is their utility limited to that purpose, for we often use them on the dinner table, placing them under candlestick stands or anything else that seem to want such a vase. Usually we have two or more sizes, which with care last several days at the dinner-table; but for hanging-up against a wall there ought to be flowers, either natural or artificial, in the centre to conceal the needlework.

Fruit has by some been introduced into such decoration, but I am no advocate for it, unless some special purpose, as a thanksgiving decoration or something of the kind, call for it; nevertheless, I know it is often made use of. I believe my first essay at such things was in forming the date 1828 with nicely coloured Apples, through which a wire was forced and bent to the required shape, and it being for a ball-room on the last night of the year, a little contrivance was required to enable the 8 to be converted into a 9 after midnight. Since that time there has been wonderful changes in such matters, and sometimes Oranges and other fruits are fixed where I would be more inclined to call them grotesque than pretty; but I fear I must beat a retreat in this matter, or someone will be asking if the whole thing is not more grotesque than beautiful; but as something of the kind is always looked for some time during the winter, whether it be the dressing of a Christmas tree, the embellishment of the church, or the decoration of the ball-room, all of which are more or less indebted to the greenery in which the gardener deals, the above remarks on the way such things may be worked-up may, perhaps, be of service to those who may not have had much experience that way.—J. ROBSON.

### SUMMER PINCHING AND PRUNING.

I wish to elicit the opinion of orchard-house cultivators (particularly those of the north), on the propriety or impropriety of summer pinching. Here I have for some years entirely abandoned the practice with the best result. I have healthy trees, well-ripened wood, and abundant crops. My trees grow freely. I soon have the wood close to the glass bearing admirably. The only pruning they have is the heading-down of the too vigorous shoots after the fall of the leaf and the cutting-out of shoots where I think them too much crowded.

My trees are chiefly in 16-inch pots, and are repotted every second year with soda and a little bone dust; they are also freely watered with weak liquid manure all through the summer.

Some years since I was struck with the remark of an itinerant Scotch gardener, who, when exclaiming against summer pruning, offered this illustration:—"It pits them out o' temper; did ye ever see a clipped Thorn hedge with a crop of haigs (haws)?"—T. G., *Glintheroe*.

### COLE ORTON HALL.—No. 2.

THE SEAT OF SIR GEORGE H. BEAUMONT, BART.

On page 446 this celebrated garden was referred to and some of its features were described, its poetry quoted, its Conifers mentioned, and its flower garden engraved. Before noticing the useful—the fruit-growing—department, for which Cole Orton has long been famed, a few other ornamental trees and some other attractions of the place merit a brief notice.

How fine the trees are the accompanying engraving testifies. The Elm, even for an Elm, is a giant; the Holly—a massive cone, its lower branches sweeping the grass—is a most worthy specimen; the *Cryptomeria* a model of health, and the dark

*Araucarias* contrasting with the light stone mansion, and which partly surround it at regular intervals, constitute striking features in these richly-ornamented grounds—grounds which are not merely ornamental, but are memorials of those who were eminent in art, science, and literature, and who enjoyed the solitude of this garden.

I have mentioned the memorials in "tree and stone" of Scott, Coleridge, Wordsworth, and others, and worthy of special note is the living arch of Limes, the avenue of these trees leading to the monument erected in honour of Sir Joshua Reynolds. At the entrance are busts of Raphael and Michael Angelo. The avenue is ornamentally paved with coloured pebbles and tiles. The Limes on either side are straight columns, their branches arching overhead delineating in a strikingly natural manner the nave of some vast cathedral. At the end is the urn, on which is inscribed at the request of Sir G. H. Beaumont—

"Ye Lime trees ranged before this hallowed urn,  
Shout forth with lively power at spring's return  
And be not slow a stately growth to rear  
Of pillars, branching off from year to year,  
Till they have learned to frame a darksome aisle  
That may recall to mind that awful pile  
Where Reynolds, 'mid our country's noblest dead,  
In the last sanctity of fame is laid;  
There, though by right the exulting painter sleep,  
Where Death and Glory a joint sabbath keep,  
Yet not the less his spirit would hold dear  
Self-hidden praise and friendship's private tear  
Hence on my patrimonial grounds have I  
Raised this frail tribute to his memory.  
From youth a jealous follower of the Art  
That he professed, attached to him in heart!  
Admiring, loving, and with grief and pride  
Feeling what England lost when Reynolds died."

This attractive memorial was not only raised in honour of a great painter, but another painter, Constable, subsequently made it the scene of one of his finest works, which was sold to Louis Philippe, the late King of the French, for 650 guineas.

I will now pass to the north lawn and note some of the Conifers which are there flourishing. Each specimen is isolated from the rest, and as many of them are planted on gentle knolls their beauty and proportions are seen to the best advantage. Many of these trees—for trees they are—are not only of unusual dimensions, but of exuberant vigour.

The soil of Cole Orton is specially adapted to the requirements of trees. A Beech tree, for instance, on one of the lawns has a stem nearly 85 feet in circumference—a majestic specimen, a monarch of its kind. But to the Conifers. A pair of *Pinuses* (*macrocarpa* and *exceles*) are veritable timber trees; they are not of close growth, but are highly distinct; their heights are 35 to 40 feet, and the girth of their stems 5 to 6 feet. On this lawn *Araucaria imbricata* is also equally striking—not by its mere height, for its leader has been repeatedly broken—but by the size of its stem, which is 6 feet in circumference, and the rude health of the specimen. Of *Cryptomeria japonica* there is a grand example 80 to 35 feet in height, dense, and of the richest green; the branches, laden with cones, of this fine pyramid sweep the lawn, and at their extremities measure 25 yards in circumference. Another notable specimen is *Picea Nordmanniana*, 25 to 30 feet in height, in splendid health and of perfect symmetry; and there is a smaller yet admirable example of *P. amabilis*. Here, too, also flourishes the true *Cedrus atlantica*, the elegant and well-furnished specimen being nearly 30 feet in height; and considerably larger, and still richer, is a noble cone of *Taxodium* (*Sequoia sempervirens*; this magnificent example of the Red Wood tree is 40 feet in height, the result of twenty-five years' growth. Here also are *Deodars* of the same age, and many other specimens which it is not necessary to enumerate; those named will give a sufficient idea of the Conifers at Cole Orton; they are such as their owner, Sir G. H. Beaumont, may be proud to possess. The greater number of them were planted by Mr. Henderson, who has remained to see them attain to their present state of perfection.

Besides the many attractive features within these grounds the views beyond and from them are most extensive and picturesque. From one point a pleasing glimpse is afforded of the village of Cole Orton; from another the distant hills of Derbyshire, and the ruins of Grace Dieu, &c., are seen, and from the terrace is obtained a magnificent panoramic view of Charnwood Forest, with Belvoir Castle in the distance. Overlooking this grand expanse of country, and at the end of an avenue, is an architectural seat and tablet, with a tribute to the memory of one of the family—Francis Beaumont the

dramatist and poet. An extract from this memorial may appropriately close the poetry of Cole Orton.

"Beneath yon eastern ride the raggy bound,  
Bugged and high, of Charwood's Forest ground,  
... There, on the margin of a streamlet wild,  
Did Francis Beaumont sport an eager child;  
There, under the shadow of the neighbouring rocks,  
Sang youthful tales of shepherds and their flocks;  
Unconscious prelude to heroic themes,  
Heart-breaking tears, and melancholy dreams  
Of alighted love, and scorn, and jealous rage,  
Which with his genius shook the hushed stage.  
Communities are lost, and Empires die,  
And things of holy use unhallowed lie,  
They perish; but the intellect can raise  
From airy words alone a pile that ne'er decays."

And now I will change the scene and theme, from groves  
passing on to Grapes, and from Pinques to Pines, The kitchen

gardens are but a short distance from the pleasure grounds, and are approached through bowers of evergreens leading to an orchard, the border by the side of the walk containing standard Roses of unusual vigour, their strength being sustained by good soil, rich feeding, and very close pruning. The fruit trees in this orchard are some of them old and scraggy, yet healthy, and yield good produce; but besides the fruit the Mistletoe growing on the Apple trees invites attention. [It is specially noticed by a correspondent on page 561.]

Entering the walled garden, which is about two acres, the borders again being lined with Roses—what a place for Roses!—we see the vineries on the south wall, and could not resist the involuntary mental inquiry, Are these the structures which for a quarter of a century produced the Grapes which won so many prizes and medals at the Royal Horticultural, Royal Botanic, and other Societies' shows? The houses are neither

Fig. 117.—COLE ORTON H LL.

large, lengthy, nor lofty, but just such common-place erections as were placed in ordinary gardens half a century ago, and the Vines are certainly as old-fashioned as the houses. Their gaunt stems rise from the ground, and their branches are trained "any way," one Vine covering a roof and the shoots disposed according to the one governing condition that the foliage can have light. They are pruned, too, on "no principle," as some might call it, yet on the principle of selecting and cutting to the best eyes, let them be situated where they may. That is how, so far as regards training and pruning, Mr. Henderson has "swept the boards" on so many occasions by the splendid quality and superb finish of his Grapes. It may be urged that this mode of culture is without "system," but rather should it be regarded as the fruit-producing and prize-winning system of which Mrs. Henderson, with just and commendable pride, did what the veteran winner did not care to do—gave abundant proof by such a display of gold medals as have probably never been won by one man. Mr. Henderson showed until he was tired of showing, and won until he was tired of winning, but he grows good Grapes by his old "no system" mode of culture, and on the same old Vines. His mantle has now fallen on Mr. Coleman who was one of his pupils—a worthy pupil of a worthy tutor.

But in worse than these old houses, or at least in a structure still more unlikely and uninviting, have the conquering Grapes been produced. And now I am going to state something wonderful, almost incredible, yet true. At the end of the vineries

is an old brick pit. It was once a Pine pit heated by dung, the bottom being arched forming a chamber beneath in which to place manure. Thirty years ago Mr. Henderson converted this brick frame (for that is what it is) into a vinery by placing in it a little more than a foot of soil and planting with Vines, the canes being trained near the glass. The pit is now heated by a hot-water pipe (no bottom heat), the lights push up and down—there are twelve of them—and the bed in which the Vines (seven) are planted is 7 feet wide. It is from this homely pit that the aristocratic Grapes have come. And now for the marvel—this twelve-light pit has produced Grapes which have won prizes of the value of £300. Is not this an achievement unparalleled in the annals of Grape culture? Eleven pounds of fruit to the square yard of glass is the annual produce of this pit. The canes are trained "any way," and pruned as before to the "best eyes." The wood is stout, and exceedingly short-jointed, and the foliage in October possessed the thick leathery texture of that of the Fig. It is hardly necessary to say that these Vines have been top-dressed and fed with the right food, and in the right quantity, and at the right time. On these Vines I make only this short comment: they show conclusively what may be done with a small amount of soil if properly attended to, and that—I make no secret about it—were I essaying the production of Grapes involving the least outlay in preparations and fuel I should "go in" for the pit culture à la Cole Orton.

At the other end of the vineries is a corresponding pit,

where Peaches are successfully grown in the same way as are these remarkable Vines.

There is another short range of vineries planted with Vines of more modern date, which were carrying excellent crops of highly finished fruit. The outside Vine borders (and I think all are outside save that of the pit) are heavily dressed with rich manure annually, and which is never removed. No fear of the roots leaving a rich feeding ground like that and darting into the subsoil. The surface is simply netted with them, and cannot be dug, and hence the short-jointed wood, leathery foliage, and finely finished fruit. It is just the old lesson over again, but how slow is the world at learning it!

I have yet to note the Pines. The notice needs only to be brief. They are grown in brick pits, the lights pushing up and down. There are four pits of twenty lights each. The plants are grown on the labour-and-fuel-saving system. They are not potted. The suckers are planted one year, and they fruit the next, and such fruit! For instance, in October the fruit had been out and the plants cleared out which had been inserted as suckers in the preceding September. If an occasional plant fails to fruit the first season, its fruit, Mr. Henderson says, never "plumps" so well as the yearlings, because the "steel has been taken out of the soil and the roots have lost their vigour." "If," says he, "you want the best Pines in the shortest time select big suckers 'as long as your arm' and plant them early in September, and within the twelve-month you will have more 'eight-pounders' than anything else." The condition of the plants justified that assertion. The Pines are grown as cool as possible, two 3-inch pipes affording, I think, all the artificial heat; but then the pits are narrow and shallow, so that no more air is heated or cooled than is absolutely necessary. It is the most economical and effectual example of Pine-growing which, after rather extensive travels, has come under my notice.

The garden walls are covered with well-trained and fruitful trees, many of them old, especially the Peaches, which looked like octogenarians which had been cut down and made new again. They produce splendid crops of fruit, illustrating in a convincing manner the force of Mr. Luckhurst's advice on this mode of treatment on page 461.

This instructive garden I now leave. Fortunate it is that it is in the possession of an owner like Sir G. H. Beaumont, whose taste in improving and care in sustaining it is everywhere evident, and who generously permits it to be enjoyed by all who can appreciate the "beauties of nature and of art." Fortunate also is it in having had for a period so lengthy and so fruitful in good results the superintendence of Mr. Henderson, who, with his helpmeet, I thank for their three hours' attention. To Mr. Henderson I must also apologise lest I have seemed to praise (which I know would be distasteful) when I have guardedly endeavoured only to state facts and speak the truth soberly.

Cole Orton is about two miles and a half from the railway station of Ashby-de-la-Zouch, and there are few gardens which will better repay a visit—in June when the Roses are in bloom, or in August when the fruit, flowers, and trees are in perfection.—J. W.

[A correspondent has sent us the following notice of Cole Orton churchyard:—"It was the early spring when I was there, and the flowers in the churchyard were extremely pretty; some on the graves, and others on the grass and by the sides of the walks. At the entrance-gate there was a neat board just inside the churchyard with the following words:—"It is requested that no one will pluck the flowers in God's Acre." This name is taken from Longfellow's poem, which begins—

'I like that ancient Saxon phrase which calls  
The burial ground God's Acre.'

And concludes—

'This is the field and acre of our God;  
This is the place where human harvests grow.'

Cole Orton is a churchyard worthy of imitation."]

#### VINE ROOTS IN SEWER.

In reply to "MUSCAR" regarding Vine roots finding their way into a sewer, as mentioned in the Journal of the 9th inst., page 505, I fail to see why it is so important he should know where the circumstance occurred. I assure him the case was as recorded, and from that circumstance alone I have drawn certain deductions that I doubt not have contributed in no small degree to the fair amount of success I have attained in

the cultivation, under varied circumstances, of the Vine. There are reasons (known to the Editors) why I do not wish to name the place, and trust "MUSCAR" will be satisfied with my assurance of the veracity of the statement.—J. B. S.

["J. B. S." is right; the garden no longer exists where the Vine roots penetrated the sewer. The "fair amount of success" alluded to by "J. B. S." means, we can testify, that he grows some of the finest Grapes which have ever been produced in Britain.—Eds.]

#### OUR BORDER FLOWERS—THRIFT.

THE *Armeria*s are plants of dwarf compact growth, succeeding in most places if they have full exposure to the sun. *Armeria vulgaris* used to do us good service as an edging plant for walks, but now Box, edging tiles, &c., have in a great measure supplanted it, yet the pink and white varieties alternately planted as an edging produce a charming effect. There is little difference of appearance in the habits of the species; some are rather stronger growers than others, but the greatest distinction is in the height of the plants and colour of the flowers.

*Armeria maritima*, the Sea Gillyflower, is found in salt marshes by the sea; either this or a variety closely allied to it is sometimes met with in some of the inland and upland districts. *A. cephalotes* is one of the brightest of the race and very attractive, the colour approaching bright crimson; it continues long in bloom, and is a capital plant to grow where out flowers are in request. It should be in all gardens. *A. montana* is a very desirable kind, well adapted for the rockery, but seldom seen. *A. alpina* is very similar to *A. vulgaris*; it is of very dwarf compact habit, suitable alike for rock or border. *A. nana* is one of the least of the family, but being a native entitles it to a place on our rockery or borders.

The *Armeria*s grow well in a good tenacious loam mixed with decayed vegetable matter and sand. The plants may be increased by division in spring or autumn, and they are the better for being removed occasionally. Sometimes in wet situations the plants damp-off; this ought to be guarded against by good drainage.—VERITAS.

#### HIVE BEES AS PREDATORY INSECTS.

NOTICEABLE amongst the incidents of the past autumn is the fact that both in the weekly and the daily press there have appeared denunciations of our esteemed friend the honey bee, who has been portrayed by the imaginative pens of some correspondents in such gloomy colours that it is quite needful to consider what may be said or done to alter the aspect of the affair. The bee-keepers will have their own way in the business, and I do not intend to speak of it from their standpoint; but as a general observer of insects, especially those which are beneficial or injurious to the garden or orchard, I must assert my belief that the mischief bees have done in the latter during 1875 has been exaggerated, or at least misapprehended. Peaches, Apricots, Plums, and Pears seem to have been much visited by bees, it is true, more in some districts than in others, as we should expect; and a pretty common conclusion by gardeners and others has been that these incursions have to do with the scarcity of wild flowers, driving the bees to whatever resources might be at hand. Many a paterfamilias, perhaps, taking his morning walk in his own domain, has seen the bees in full play about the fruit, and his gardener has had his tale to tell of the destruction of the fruit by these insects; and by-and-by at the breakfast-table a chorus of uncomplimentary epithets rises which are only partly deserved by these diligent honey-collectors. I do not deny that bees will attack fruit that is perfectly sound, yet I also maintain that it is much more frequently the case that the fruit they pull to pieces has previously been preyed upon by some smaller and unobserved insect, or has suffered from a fungoid or other vegetable malady. These causes of decay are missed, and the bee, the "last on the scene," receives all the blame.

At the commencement of last summer we had unfavourable weather, and honey may have been scarce in many districts; but it was not then that the proceedings of the bees were complained of, since the fruit could not have been forward enough to invite their attacks. Sunny weather afterwards produced an abundance of flowers, and I hardly think this explanation will account for any peculiar eagerness bees have shown in resorting to fruit trees. Another view suggested by some, and in which the acute editor of the "Entomologist" sees some-

thing, is that the undoubted scarcity of wasps may have encouraged the bees in their inroads where in ordinary years they have to compete with the wasps. But is it really true that wasps do frequently chase bees off from fruit they would otherwise attack? Possibly they are as contentious as the familiar "cat and dog," though I would not mind backing as a combatant a sturdy bee against its more agile relative the wasp. It would be curious to know whether the Ligurian bee demeans itself differently to the older denizen of our hives in respect to fruit. Some persons have gone so far as to propose that in these days of bee-keeping there should be a legislative enactment limiting the number of hives to be kept in a certain space!—O.

### MISTLETOE PROPAGATION.

As this popular parasitic plant is now in great demand, and as many attempts will doubtless be made to establish it by sowing the berries, it will not be inopportune to note its increase at Cole Orton, where it appears to grow as freely on the branches of the Apple trees as the trees themselves grow in the soil, and Mr. Henderson seems to have the same facility of raising Mistletoe from seed as of raising Radishes.

For a time he could not succeed. That was when he followed the prescribed plans of inserting the seeds in cracks of the old bark, or just within the bark in V-cut cavities, tying with matting and plastering. He then reflected, and this led him to follow Nature's plan. The seeds, he concluded, must be placed on the bark and not under it; and if on it, surely the radicle of the germinating seed will more readily penetrate thin, clean, tender bark than the dirty moss-covered, harder cuticle of the old branches. None can deny the correctness of that logic. That it is sound is evident by the freedom with which the berries germinate when simply rubbed on the smooth clean bark, and no further care is given to them. They are safer from birds when placed on the lower side of the branches. They are stuck on at any time when the berries are ripe, simply crushing the viscid flesh, which glues them closely to the bark. Some of the seeds which had been applied were swelling, being of the size of large peas, while others had formed young plants in various stages of growth.

In districts where the Mistletoe is not found, a common plan of sowing the seeds is after they have done duty for six weeks, near the ceiling of a dry heated room. Let those who desire to establish this hardy parasite affix the seeds in the manner mentioned, but before they have undergone the drying process, and the probability is that a portion of them will germinate.—W. J. B.

### ROSES ON THE ROOTED BRIAR.

I AM glad to observe that many rosarians have adopted the plan recommended by me in this Journal in October last year; that is by putting down young Briar shoots as cuttings or slips in October and November in the ordinary way, and have fine rooted stocks ready for budding in the following summer. I have letters from various parts of the kingdom from those who have tried my plan, and in every instance they speak in the most eulogistic terms of the quantity of fine fibrous roots produced, and the vigorous growth of the head. I had about eighty Briars transplanted early last month which were budded in July; they were all most beautifully rooted, quite as well as some Manettis I was raising at the same time, and in some cases much better. This is certainly saying a great deal for my method.

Your correspondent, "R. C.," says he had not so much success by this plan as I gave myself credit for. I do not wonder at this, for much depends on the season, also on the nature of the soil and the care taken of the stocks, and very much depends upon the kind of stock selected. I have had a good deal of experience in this matter, and I can assure my friend "R. C." that I rather under than over-rated my success in growing Briar stocks. An instance just occurs to my mind of a gentleman who put down fifty Briars according to my directions; he complained to me that nearly the half of them died, but gave me credit in saying that the remainder did well and rooted most beautifully—much better than any Briars he had ever seen, and he intended following out the system. Now I visited that gentleman's place in summer, and I was rather surprised that so many of his stocks grew. In the first place the soil was a stiff red clay, and the spring being very dry the clay soil was so full of cracks that my surprise was that any of the stocks grew. The soil was never watered, no protection

given, and the stocks very small and of the very worst sort. Nurserymen will agree with me when I say that many good plants are lost simply for the want of a little attention and a little common sense in their treatment.

I find Briars succeed best in a cool rich deep loam, and the soil requires to be kept moist in dry weather. My method is to dig deep and keep the ground loose; plant them about 6 inches deep and 1 foot apart, then to cover the surface of soil with a few inches of straw or any kind of litter. This keeps out frost in summer, and prevents evaporation in the drying months of spring and summer; this is most essential, for the Briar suffers much from drought.

"R. C.," I have no doubt, put in his Briars too soft; unless they are well ripened they are sure to die. They should be of this year's growth, red in the bark, with well-developed buds and taken off with a heel. If "R. C." will attend to the above directions I have no doubt he will be successful.—JOHN TURTLE, *Peacefield, Portadown.*

### PORTRAITS OF PLANTS, FLOWERS, AND FRUIT.

*Calochortus citrinus.* *Nat. ord., Liliaceae. Linn., Hexandria.*—"This is a fine new species of that section of the genus *Calochortus* specially favoured by cultivators. The species known previously are *C. venustus*, *Leichtlinii*, *Gunnisoni*, *splendens*, *macrocarpus*, and *luteus*. They all come from either British Columbia, the Rocky Mountains, or California, and, with care, are hardy in our London gardens. The plant flowered last summer with Mr. G. F. Wilson in a cool greenhouse at Weybridge, the bulb of which was given to him by Mr. Elwes."—(*Bot. Mag., t. 6200.*)

*Diuris alba.* *Nat. ord., Orchidaceae. Linn., Gynandria Monandria.*—"D. alba is most closely allied to, if not a slender variety of *D. punctata*, *Sm.*, differing in the flower not being lilac and spotted all over. It has also a more northern range, from New South Wales to Rockingham Bay, whereas *D. punctata* ranges from the former district southward to Victoria. The plant flowered in August last in the open border from tubers sent by Thomas Moore, F.L.S., Director of the Sydney Botanic Garden."—(*Ibid., t. 6201.*)

*Gladiolus cooperi.* *Nat. ord., Iridaceae. Linn., Triandria Monogynia.*—"When Mr. Thomas Cooper was travelling in South Africa on behalf of Mr. Wilson Saunders, he paid special attention to these ensiform-leaved *Gladioli*, of the group of which *G. cardinalis* and *G. psittacinus* are the familiar garden representatives. He discovered, or at any rate brought into notice in Europe, no less than three very striking new species, of all of which bulbs were sent home and duly and successfully cultivated at Reigate, so that they all are now established as inhabitants of our gardens, enlarging materially the groundwork upon which hybridisers can carry forward their experiments. It has now been spread about in gardens for several years, but has never been botanically named or described."—(*Ibid., t. 6202.*)

*Dicabellone barklyi.* *Nat. ord., Aselepiadaceae. Linn., Pentandria Digynia.*—"The first discovery of this interesting plant is due to H.E. Sir H. Barkly, who sent a sketch of the plant in January, 1874, having found it three years previously growing in the Karoo, near the Orange River. Shortly after Dr. Shaw, who, as well as M'Lea, had found it in the same locality, sent to Kew specimens in spirit, and a careful analysis."—(*Ibid., t. 6203.*)

*Pernettya pentlandii.* *Nat. ord., Ericaceae. Linn., Dicoandria Monogynia.*—"A little evergreen shrub, a native of the temperate and colder regions of the higher Cordilleras from Venezuela to Chili, ascending to near the limit of perpetual snow, and varying greatly in stature, habit, and size of leaf. The form approaches to the var. *parvifolia* of Weddell (*P. parvifolia, Benth.*), which inhabits the Andes of Ecuador, as Pichincha and Cotopaxi, and has smaller leaves and short pedicels. *Pernettya pentlandii* was raised by J. Anderson-Henry, F.L.S., from seeds sent from an elevation of 14,000 feet on the Quitonian Andes by his late correspondent Dr. Jameson; it flowered in June, fruited in November, and proved quite hardy at Trinity Lodge, Edinburgh."—(*Ibid., t. 6204.*)

*Calathea leucostachys.* *Nat. ord., Marantaceae. Linn., Monandria Monogynia.*—"This is another fine Central American species of *Calathea* introduced by Messrs. Veitch, to whom also is due the credit of introducing the *C. tubilipatha*, and *C. Veitchiana*. As a species the present comes nearest the *C. Warzewiczii, Klotzsch*, ("Regel Gartenflora," 1866, t. 575),

especially in the form and colour of the spike, bracts, and flowers, but differs wholly in habit, in being much more villous, and in the sessile or subsessile broader leaves. *Calathea leucostachys* flowered in Mr. Veitch's establishment at Chelsea in October, 1874, from plants sent from Costa Rica by Mr. Endres."—(*Ibid.*, t. 6205.)

**PEAR**—*Louise Bonne d'Avranches Panachée*.—One of the most useful of dessert Pears in its season (October) is the *Louise Bonne* of Jersey, one of the synonyms of which is *Louise Bonne d'Avranches*. This excellent Pear is a variety which originated, as Dr. Hogg tells us, in a bud-sport, and in consequence of its beautifully marked fruit was distinguished as the striped variety (*panachée*). The Striped *Louise Bonne*, as may indeed be concluded from its origin, is in all respects similar to the well-known *Louise Bonne* of Jersey—or *Bonne Louise*, as some say it should be called. It is a good grower and a good bearer; it succeeds well as a pyramid on the Quince stock; it is invariably of good quality and flavour; it may be had for some time in use in the autumn season; and a good sample nicely coloured forms a dish of most tempting fruit for the table, and one, moreover, which will bear the test of trial, seeing that its quality equals its appearance."—(*Florist and Pomologist*, 3 s., viii., 281.)

### ROSES.

THE winter of last year here was hyperborean, the spring late, and the summer cold and wet. Nothing could be finer than the first bloom of *Roses* beginning about June 10th. After the first bloom orange fungus set in; still the plants have done well; and I finished the season December 12th.

Orange fungus destroys healthy leaf-action; hence in time the leaves dropped off, the plants had no power of breathing except through the bark. Till new leaves are formed the plant has no power to elaborate the sap; hence sickness. I have just cut out the *débris*, and cut off the secondary and unripe growths, and the plants look like the masts of ships. I did not send my ideas to Mr. Hinton for these reasons: the summer was too wet to judge correctly of scents, and I did not know the date of *Roses*. Let me here say how much we all owe to Mr. Hinton.

As far as I recollect the best scented Hybrid Perpetual *Roses* are *Laoharme's Van Houtte*, the *Duchess of Norfolk*, *Baron Chaurand*, *Pierre Notting*, *Prince Camille de Rohan*, *Madame Knorr*, *Madame Clémence Joigneux*, *Monsieur de Montigny*, *Gloire de Vitry*, and *Baronne Prevost*. Of the newer *Roses* sent here these are the best and good. *Star of Waltham* the best. These are good: *St. George*, *Pierre Seletzaki*, *Souvenir de John Gould Veitch*, *Paul Neron*, *Maxime de la Roeheterie*, *Etienne Levet*, *Claude Levet*, *Madame Naeury*; and for garden ornamentation, *Olga Marx* and *Hortense Mignard*. No new *Rose* has gone through the trying season so well as *Veitch's Duchess of Edinburgh*. It appears to be a *China Rose*, and is a valuable colour for *Tea Roses*, whose chief defect is that they are wanting in high colours.

I regret that the later *Roses* are sadly deficient in scent. My opinion is that the grandest *Roses* of late are *Louis Van Houtte*, *Marquise de Castellane*, *Countess of Oxford*, *Maxime de la Roeheterie*, *Star of Waltham*, and *St. George*. It takes several years on strong and proper stocks, and in proper soils, to come to a reliable adjudication of the value of *Roses*.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

### REST.

EVERYTHING that is endowed with vitality must have rest. The least infringement of this law is followed with a corresponding amount of exhaustion and suffering. Mental or physical work, or both combined, persisted in without a corresponding periodical cessation and repose, sooner or later ends in the premature wreck of bodily and mental powers. This age of fiery competition and activity affords ample proof that the law of periodical and sufficient rest cannot be ignored with impunity. The body that is subject to over-much of physical exertion too soon becomes a wreck of shrunken tissue and physical suffering. The overworked brain softens and refuses to comply with the effort of thinking, or even a worse and more violent fate overtakes it.

This same law of rest reigns as inexorably and prominently—or even more so—in the vegetable kingdom. It does not matter in what zone or latitude the herb, or shrub, or tree

exists; it must, under some condition or other, have its season of rest once in twelve months, or it will terminate its existence prematurely by an effort which it was never designed to make. This age of much and unseasonable forcing of flowers and fruits affords ample proof of this. If a resting season, at one period or other of the year, is not recognised and provided for, a plant very soon exhibits unmistakable signs of debility: and if subject to conditions that keep its vital powers active for any lengthened period without an intervening and a sufficient resting season, it ultimately succumbs to the outrage on its vital powers.

This law is therefore one which cannot be too sacredly recognised and acted upon by all who have to produce fruits and flowers, especially at times which are termed "out of season." It is a tolerably severe ordeal for any plant to be subjected to artificial conditions which will cause it to produce and bring to maturity a crop of either flowers or fruits at a time which necessitates the performance of its functions throughout a season when the stimulating powers of sunlight and heat are at their lowest. To do this, after even a sufficient term of resting, entails a strain upon the system. To persist in attempting to accomplish such a result without a proper term of rest is as certain to end in failure as that two and two make four. There is not a law in the universe that can be disregarded with impunity, and this one of rest asserts its prerogative with emphatic certainty.

It does not matter to what part of the world we look, vegetation under natural circumstances is more or less provided with a season of cessation from active growth. In this country and other northern latitudes rest is induced gradually by autumn, and is carried on to its fullest extent by the lower winter temperature and the comparative absence of the stimulating power of light. If we turn to the tropics we find the same effect produced by the dry season, which bakes the earth to a comparative crust, and dries the air to an extent we in this country never experience.

Here, then, is a power which the successful forcer of flowers and fruits cannot afford to treat in any way but with the utmost consideration and care. It is not necessary to ransack far into the gardener's duty to find practical illustration of the necessity of affording all plants under his care a sufficient season of rest, not to be able to show where the disregard of this point injuriously affects results. Take for instance, the enormous number of pot Vines which are annually grown and forced to produce early Grapes—that is, Grapes in March, April, and May. We do not hesitate to say that there is not one out of every hundred grown that has a sufficient season of rest after they have matured their season's growth; and the crops they bear are proportionally inferior. It has been frequently proved in practice, that, if a Vine has a long season of rest after being well ripened, it is one of the most tractable plants to excite into growth at almost any day of the year. But the converse of this is true of it if it is thrust into heat only a few weeks after it has shed its leaves, or, as is sometimes barbarously practised, they are torn off with the hand. We hold it to be impossible to grow and mature Vines sufficiently early the first season from eyes to make adequately strong Vines that will ripen in time to have rest enough before they are put in heat in November and December. And if this condition of rest is not afforded them they require an unnaturally high temperature to start them in time to answer the purpose for which they are intended. Need it be said that they must break weakly, and have a growth forced out of them with a vengeance, at a season when the natural impulse after sufficient rest is needed more than at any other time? To obviate these unfavourable conditions, and fully recognise and reap the full benefit of a sufficient period of rest, it is necessary to fall back on Vines struck from eyes the previous year; to start such at the turn of the season in January under conditions where they can have as much light as possible, and be grown-on without a check, and so made to thoroughly ripen their wood to a nut-brown colour, and then be subject to a cool position to rest for three or four months before they are placed in heat. Vines grown crowded together and ripened late—perhaps denuded of their leaves with the hand, and then started early without a season of repose—are something like a man or beast working day and night without rest or sleep; and the results cannot fail to be unsatisfactory just in proportion to the faithfulness with which natural conditions and laws are violated.

It were easy to multiply illustrations of this matter, but the case of the Vine is just a type of what is more or less applicable to everything in cultivation. If the Pine Apple is kept grow-

ing in a too crowded condition and by the unvarying application of moisture and heat, the fruiting becomes a matter of the greatest uncertainty; whereas, if the plants are vigorously pushed on to make their growth under the influence of sunshine, and subjected to a rational sliding-scale as regards heat and moisture, they can be fruited with a certainty. In short, if the law of nature as regards a resting period is imitated by different means at different seasons they answer their purpose. Seven years ago we had to do with house upon house full of Pine plants that should all have fruited the previous summer and autumn, but which instead grew on to be of great stature. Their growth was arrested by rather a violent process. They had a rest, with more room to allow air and light to play upon them, and every one started and fruited with comparative satisfaction. The want of rest, and a prolonged season of growth under the influence of heat and moisture, had made leafy giants of them. They had no rest to induce any disposition to fruit. Except under exceptional circumstances, all violent, sudden, and unnatural resting is to be as much deprecated as no resting at all. That maturity and resting which is brought about by subjecting plants to a drying and roasting process is not maturing and resting—it is starving and semi-extinction. To ripen, for instance, the late wood of Peach trees by drying the soil, is a putting of the system to rest by laying violent hands upon its functions, not by building it up and maturing it. A judicious nourishing by liquid manure, a warm atmosphere, and as much light and air as possible, produce maturity and put the system to rest full of latent power and vigour, which, after it has been properly rested, comes into play like a giant refreshed with sleep.

Not only is it necessary that the resting period should be of sufficient duration—it should also be complete by subjecting the plant to a temperature sufficiently low and steady not to excite in any way that is calculated to cause functional activity which is not consistent with resting as nature rests. In the case of deciduous subjects there is generally not so much fear of this condition being infringed; but in the case of plants that are termed evergreen there is reason for believing that a comparatively high winter temperature has too long been practised, and that a season of comparative rest and inactivity in their case also has not been fully recognised. More recent experience proves beyond all doubt that many plants that are natives of even tropical America and the South Sea Islands, and other warm parts, can be subjected not only with impunity to a much lower temperature than has long been the rule in our stoves, but that they are actually benefited by such treatment. We have too long kept out of the count our comparative absence of light and the weakness of constitution that is the inevitable consequence of a stimulating temperature without the amount of sunshine that is necessary to vigorous tissues; and so Orchids that are subject to a heat that is out of proportion to sunlight in winter make lean lanky leaves and flowerless growths; or if moisture is not carefully measured out to the atmosphere, they, in some cases, have the juices sucked out of their leaves—they become yellow, flaccid, and eventually drop off when they are most required. A comparatively low temperature, with sufficient moisture in the air to counteract the evil effects of fire heat, is surely a more rational winter treatment, and one which allows of that rest which insures a vigorous inflorescence and growth afterwards.

All plants which have a disposition to grow in our hothouses in autumn and winter indicate by their so doing that their summer quarters should be cool and not roasting. There is much talk of heat free of cost now-a-days, but it may safely be averred that much heat has been worse than wasted in keeping winter temperature rigidly up to certain and injuriously high points; and if the systems which are said to supply heat free of cost lead to an indulgence in high winter temperature, they will sacrifice at one end what is gained at the other.

Our space counsels us to close our remarks, but we cannot do so without saying that we consider the horticulturists' golden rule to be: Ripen your season's growth properly, and then give a long period of complete rest.—(The Gardener.)

#### IVY.

At a recent arrangement for our church decoration at Christmas the employment of Ivy was deprecated. Is this objection prevalent? The name here is pronounced Iv-ry.—GERTRUDE.

[The correct pronunciation is I-vé. We presume that you live in a midland county. The name is Anglo-Saxon, and in

that language it is spelt Ivith. We know of no reason for objecting to Ivy, unless the canon issued by a Council at Bracara is allowed to be an authority. Prynn in his "Histrio-Mastix," cites other Councils forbidding Christians "to decke up their houses with lawrell, yvie, and greene boughes," quoting as a reason from Ovid the line "*Hedera est gratissima Baccho*"—that is, "Ivy is most acceptable to Bacchus."—Eds.]

#### NOTES ON VILLA AND SUBURBAN GARDENING.

**VIOLETS.**—It is now just upon twelve months ago that I saw in a cottage window a splendidly-bloomed plant of the Neapolitan double Violet in a pot. On inquiry I found that it had been given to the parties just before it came into flower; but its appearance at that dull time of the year was so suggestive and its fragrance so refreshing, that I have thought a few remarks upon the culture of Violets, both in pots and planted-out, might induce those to bestow on them some attention who have not hitherto done so.

I consider few ought to neglect devoting a corner to Violets where they can have a little protection afforded to them. But the principal and most successful way to grow the Neapolitan is to prepare a small piece of ground on, say, a west aspect, but others will do, though perhaps not so well; dig it deep, and add a good dressing of manure if the soil is not rich (this may be done during the winter), and at planting time add a coating of fine leaf soil, and break the surface down, forking the whole lightly over. When the old plants have made their growths, which will be early in May if the season is favourable, take up the runners with a root to each if possible, and prick them in about a foot apart, keeping those that have roots separate from the others, as there may be a difference in them in the autumn. They should be slightly shaded in hot dry weather, likewise watered when needful. They soon establish themselves if care is taken of them. The summer treatment consists merely in keeping the ground hoed and free from weeds. The little runners which they throw out—some sorts more than others—should be picked off; this adds much to the strength of the parent plants, and by autumn they will become quite stocky and have formed good crowns. By the middle or end of September most of them will be throwing up some flower buds, and they will then be ready to plant out in different little nooks and corners near the windows and paths where the sun can reach them; but the best of them ought to be taken up carefully, and if a frame can be spared for them, and be placed on an exhausted dung bed—such as has grown Cucumbers or Melons—and a few inches of soil placed with that already there, the plants will thrive in this admirably. They should be about 8 inches apart, and be well watered at the time of planting, and for a time should be kept rather close. Flowers will soon begin to appear of the finest quality and highest fragrance; but it is not well to allow the flowers to remain on the plants, but they should be picked and transferred to vases or glasses, and if placed in rooms their fragrance will be much admired. It must be remembered that during the dull winter months many leaves will damp-off. These must be constantly kept cleared away, and the atmosphere of the frame must not be kept too wet in bad weather, or many of the flowers will decay also. Some plants ought also to be potted at the same time and placed in the frame to be treated as the others. Excepting when they are coming into bloom they should be placed where they will be somewhat drier and near the glass, in order to have them in flower all at once.

So far the above remarks allude to the Neapolitan variety, which is the best for forcing; but there is The Ozar and Lee's Victoria Regina, producing large single blue flowers, both "beautiful and sweet," and quite hardy. There are also others, such as the single and double Russian varieties: the former is a capital kind and ought to be grown by everyone, even if the others are not. It commences flowering early in the autumn outdoors, and established plants will continue to flower throughout the winter. Here just after the melting of the late snow the flowers sprung up, looking even fresher than ever. They may be all propagated by cuttings or division. The double one is useful by flowering later than those named, but its stems are too slender for the weight of its flowers, which fall down and are often very dirty, and on that account are not so well for ladies to gather. Next there is the white one, which is indispensable on account of its colour; it is perfectly hardy and most prolific in flowers.

A few patches planted here and there among hardy Ferns, or on the little rockery among the Primroses, Snowdrops, and other spring flowers, command observation by their several good qualities.—THOMAS RECORD.

#### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

The weather has been favourable, and the ground is in good condition, which enabled us to plant out a row of young Apple

trees; the ground had been previously prepared by trenching. The space had been occupied by old trees, so that the work had to be done in a careful manner, the old roots being picked out to prevent fungoid growths from spreading in the ground, which would be injurious to the young trees. A large proportion of fresh loam was added, and a sufficient quantity of rotted manure was worked-in as well. Ground that has grown fruit trees until they are decrepid cannot be very rich in manure, and when trenching-up such borders we have manured heavily, generally applying a double dressing when the ground has been trenched about 2 feet deep. The young trees, of whatever sort, generally make a very good growth the following season, and the ground becomes matted with fibrous roots. Early in November following the trees are again lifted, the ground is trenched over—this time without any manure being added, and the trees replanted with a good deal of rich fibrous loam about the roots.

As many persons will be *planting fruit trees*, a word about the operation may not be in vain. In the first place the trees must be carefully lifted: the nurseryman will see that this is done as it ought to be if he obtains a fair price for his trees. When gentlemen try to purchase at the cheapest possible rate they cannot expect to have healthy well-managed trees. If they are more than two years old they ought to be trees that have been transplanted when they were that age, and every second year afterwards. Trees that are often removed will be furnished with plenty of fibrous roots; but the expense of removing them is considerable, and the purchaser must pay for it. It will always pay to take great pains in planting. The hole for the roots should be wide enough to allow the fibrous roots to be spread straight out, and deep enough to cover the roots and stem of the tree the same depth as it was before. Some fibrous loam is always placed under and over the roots, the soil is then levelled-in, and over it to the fullest extent of the roots is placed a dressing of rotted manure. This is not removed in spring, but is allowed to remain until it is washed away by the rains. We are root-pruning some of the Apple trees to induce fruit-bearing, and in some cases to check the spread of canker. Half the roots are lifted this season, and half the following one.

We continue to prune Gooseberry and Currant trees, and also to nail Cherry, Plum, and Pear trees on the walls. In the southern counties *Vines on the walls* carry good crops of fruit. We have seen Black Hamburgs of very good quality in favourable seasons, but this excellent sort does not always ripen. The best of all for out of doors is Royal Muscadine, which seldom fails to ripen. Those who can command glass erections will occupy their walls with some other sorts of fruit trees, and will find Peaches and the finer sorts of Pears more profitable than Vines; others who cannot afford glass structures must trust to walls for their Grapes. Next to a south aspect a wall facing west is the best. If the Vines have not been pruned they ought to be as soon as it may be convenient. If this operation is deferred until spring the Vines will bleed, and late pruning causes them to start later. We would rather prune out-of-doors Vines in November. The system best adapted for the Sweet-water and Muscadine class is that which encourages the formation of strong well-ripened young canes annually. The young wood produced on old canes is often not strong enough to produce fruit, and if bunches do show they are generally small. The old canes should be cut out when it can be done, and the young canes be laid-in in the place of them.

#### VINERIES.

We have started the early houses this week. The outside borders are protected by wooden shutters. Both outside and inside the Vines have had a watering with tepid water. The outer surface had a dressing of about a foot of fermenting material, and the shutters were again placed over it; they cause the material to retain the heat much longer than if it was exposed. The inside temperature of the houses is 45°; it may be 50° in warm nights, a rise of 5° or 10° being allowed in the day. Moisture is obtained in the atmosphere by evaporating troughs on the pipes, and from water being sprinkled on the walls and pathways. The Grapes in late houses keep better now that the leaves have been removed from the Vines, but constant vigilance is required to detect and remove any berries that show signs of decay. Those who intend to plant young Vines and have not yet made their borders ready should lose no time in doing so. It is better to have all the material ready and wheeled into its place before the winter frosts. The Vines may be planted at the same time, or they may not be planted until March. Whether the Vines are intended for an early or late house, they ought to be planted inside; any distance from 9 inches to 2 feet from the front wall will do. The hot-water pipes to heat the house are usually placed about 2 feet from the inside of the front wall; if so, the Vines had better be planted at equal distances from the wall and the pipes. The best Vines to plant are those that have been grown from eyes the same season, and we always prefer such as have been grown without bottom heat, except a little to start the eyes. Nor should the potting material be rich: turfy loam with the addition of a little crushed bones promotes a moderate growth which always ripens well. A Vine does not

require a deep hole for its roots, but they should be uncoiled and laid to their fullest extent horizontally. Some sweet moderately dry rotted loam should be placed round the roots, and when the Vines start all the eyes ought to be rubbed off except two or three at the base. Two is the usual number if the Vines are planted 5 or 6 feet apart; this distance allows a space of 2 feet 6 inches or 8 feet between the rods.

Pot Vines that were started in October will now be breaking freely. The night temperature should be 65°, or it may fall to 60° in cold weather. It is better to obtain atmospheric moisture from the paths or walls of the house than from evaporating troughs until the days are longer—say about a month after Christmas. We have grown canes of all the leading sorts of Vines from eyes put in about Christmas. The eyes ought to be taken from Vines that were forced early the previous season. The pots are put into a house with a night temperature of 55°, and a bottom heat of about 85°.

*Strawberries*.—A batch of Black Prince in 5-inch pots have been placed in the early vinery on a shelf near the glass. It is very important that the pots should be close to the glass, for when at a considerable distance from it the plants never do well, especially early in the season. We shall remove them to another house as soon as the Vines come into leaf. The temperature of the vinery at that stage is also too high. From 55° to 60° is the best for Strawberries at the time the flower trusses are thrown up. The vinery will be 65° when the first leaves are forming. When the vinery has not been available at this season we have made a dung bed and plunged the Strawberry pots in a gentle bottom heat; the lights were kept rather close, and in three weeks the plants were removed to a house with a temperature of from 55° to 60° at night, and did well. Without this start they would not have thrown up their trusses freely.

*Asparagus*.—The most general mode of forcing this vegetable is by preparing a hotbed. The best material is equal proportions of fresh stable manure and leaves. After laying on a heap for two weeks, and turned over twice in that time, the manure is not likely to heat violently; but the Asparagus must not be put in until a week after the bed is put up. By that time the extent of its heating power may be ascertained. If the heat is thought to be too strong, a layer of freshly cut turf with the grass side down will check its rising into the soil. Some persons are very particular about the age of the roots. We would not use plants less than four years old, but they may be used up to thirty years old or more. A three-light frame of the usual size will, if the plants are packed in closely, produce a dish every day for three weeks. Hotbeds are rather uncertain. Sometimes, even with the best management, the heat will suddenly rise and injure the roots. A heated pit is the best place to force Asparagus with two pipes for bottom heat, and where this can be obtained dung beds can be dispensed with.

#### GREENHOUSE AND CONSERVATORY.

Chrysanthemums are now going out, and a succession of flowers will be kept up from perpetual-flowering Carnations, Cyclamens, Cinerarias, &c. We have on previous occasions alluded to the value of the flesh-coloured Carnation Miss Jolliffe for decorative purposes and for out flowers. As a companion to it we would mention a newer variety, raised by Mr. C. Turner of Slough, named Empress of Germany. It is an immense flower of excellent form, pure white, with an occasional stripe or red flake. The flowers open freely at midwinter in a cool greenhouse. Stage Pelargoniums are now kept close to the glass, else the growths become drawn: where they are too thick we tie or thin them out. Cinerarias are also placed on shelves near the glass. When they are in bloom we place them on the stage with other plants. Bulbs and other plants that have been brought out of the forcing house should be placed in a warm corner, or the house may be kept closer for a day or two. We have finished repotting the last of the Lilliums: this ought to have been done early in November, but from an unavoidable cause it has been delayed until the present time. They were all varieties of *L. lancifolium*, and the bulbs had not started into growth. Lily of the Valley roots were also potted, about twenty-five crowns in an 8-inch pot, and the whole of the pots were plunged in cocoa-nut fibre refuse out of doors.—J. DOUGLAS.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

MALDEN (ROSES). June 21st. Mr. Hubert Bensted, Rocknow, Malden, Sec.  
SPALDING. June 21st. Mr. G. Kingston, Sec.  
HLENSBURGH (ROSES). July 12th and 18th. Mr. J. Mitchell, Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any

of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

**GRAPES IN CONSERVATORY (Learner).**—The Grapes on that portion of the Vine trained inside will be earlier and better than those from the part outside.

**FINES IN WINTER (W. B.).**—We think your plants need rest. Reduce the bottom heat 10° and top heat 5°. Do not syringe. Keep them in this state for a month, giving them one good watering. Then increase your present temperature, top and bottom, 10° respectively, watering, syringing, and preserving a humid atmosphere. These changes should be made promptly and not by gradation. Our "Fine Apple Manual," post free for thirty-two post-office stamps, will aid you.

**SPENT HOPS AS MANURE (G. R. A.).**—You may accept as a truth that all vegetable substances, whether decayed or fresh, afford nourishment to plant sooner or later if dug into the soil. Hops are especially applicable to strong soils, whether used alone or in combination with stable manure. We should be obliged by details of how you used them for hotbed-making.

**PLANTING VINES (A Constant Reader).**—We do not advise you to plant more than eight Vines in your house 24 feet long. We advise you to prune on the short-spur system. P'ant Buckland Sweetwater and Foster's White Seedling with the Black Hamburg.

**MUSCAT GRAPES NOT RIPENING (A Subscriber).**—We do not think a dressing of stable manure would prevent the Grapes ripening, unless it was laid on so thick that it prevented the heat of the sun from acting upon the border in summer, when it would be injurious. This has not been a very good season for late Grapes ripening. We object to placing manure on the borders thickly in summer. A dressing that would allow the sun to warm the surface of the border through it would do good.

**ASSESSED VINERIES (A. P. N.).**—We know of no mode of avoiding assessment.

**WINTERING FERNS (Triceps).**—The fronds of No. 1 die down. Keep the plant in the greenhouse, watering it about once a week to prevent the soil becoming quite dry. The others place at the warmest end of your greenhouse, and keep the soil healthily moist—that is, it must not be allowed to become dry, neither must it be soddened with water. All of them may, if needed, be repotted in the spring when new fronds commence growing. Give them tepid water.

**GRAPES NOT COLOURING (J. E.).**—Many Grapes besides Mrs. Pince's Muscat have coloured badly this year, but of the sort named we have scarcely seen a really well-coloured bunch. Let the Vines carry more foliage and less fruit. Overcropping is a great cause of deficient colouring.

**SHRIVELLED APPLES (X. X.).**—The cause of the Wyken Pippin Apples being shrivelled and flavourless may be attributed to their having been gathered too soon. It is a valuable late dessert kind, but requires to hang on the tree later than many other sorts.

**CELERY DECAYED (B. B.).**—Your Celery has received a check by drought in its early stages (possibly it was sown too early). It has formed seed stems and is worthless. In the future (next year) keep the roots moist, and do not apply the earth so early, and you will not have a similar failure.

**LARGE APPLE AT GHEENT (Delta).**—It was fully noticed in our report of the Exhibition.

**NEW APPLE (Constant Reader).**—Exhibit it to the Fruit Committee of the Royal Horticultural Society. If they report favourably sell the stock to a nurseryman.

**BROWN SCALE ON CAMELLIAS (J. P., Regent's Park).**—Wash the leaves on both surfaces, also the stems and shoots, with a solution of soft soap, 4 ozs. to the gallon of rain water, employing a sponge, dislodging the scale with a pointed stick. This should be done in September and again in spring after flowering, but not washing the young shoots, as the soap solution would injure the tender growths.

**TOP-DRESSING FOR VINE BORDER (J. I. G.).**—Bone dust and cow dung are good as a top-dressing, applying the bone dust alone to the surface, and pointing in with a fork, but not so deeply as to disturb the roots, and apply the cow dung to the surface 2 or 3 inches thick, adding over the dung to take away its unsightly appearance a sprinkling of turfy loam.

**PRUNING PYRAMID FRUIT TREES (F. M. S.).**—The trees having so much wood will not be overburdened with spurs. Retain all the short stubby shoots, especially of the Plums, and all the spurs of the Apple and Pear trees, cutting all other shoots upon the branches to one or two eyes of their base, or about half to three-quarters of an inch of the last year's wood, leaving the main branches a foot apart, and if thicker than that, shortening the main leader to 9 inches, and the leaders of the branches to 6 inches. It is better to have the trees rather thin than crowded with branches. Pay next season strict attention to summer pruning.

**CUTTING HEDGES OF BERBERIS AND OXYANTHERA (Idem).**—In March or early in April cut the Cotoneaster down to the level of the Berberis, trimming in the sides of the latter so as to form a hedge of equal width. Trim-in any irregularities of height or width in July or early in August.

**CULTIVATING BLACKBERRIES (Idem).**—The Lawton and the Dorchester are the best varieties, and are suitable for training to wires against oak palings. Plant 6 feet apart, and train the shoots to the wires equally disposed 9 inches to a foot apart, remembering that the shoots of the current year bear in the following, and are, after fruiting, to be cut away and replaced by young shoots for future bearing. The price per plant is 1s. 6d. to 3s. 6d., or less if a dozen or more are ordered. Not being in much demand (rather remarkable, as Blackberries make excellent tarts and jam, succeeding other bush fruit), only the principal London and provincial nurserymen kept them in stock, but any of those would procure plants for you. We cannot under any circumstances give preference to one dealer over another.

**ORCHARD HOUSE AGAINST EAST WALL (A Young Gardener).**—If your house is not to be heated we do not think you would have any success with Peaches, Nectarines, or Apricots, though it would answer for Plums, Cherries,

and Pears, and if heated would answer for the three first-named fruit trees. An east aspect is not a good one, and to have it on the west side of the wall as it may be (for you do not say which side of the wall you propose to have it), is not much better. With a low wall, say 8 or 9 feet, we should have a half-span roof, with the half-span on the wall side, the house being 21 feet in width, so that you would have 7 feet of the width covered by the back half-span, and 14 feet by the full-span. This would be very nearly equal to a span roof, and would enable you to have a good prospect of success. The house in the centre, or rather at the ridge, would, with a 9-foot wall, require to be 12 feet high, and with this pitch you would have on the open side 6 feet of side height, half of which should be glass, and to open the full length of the house, having at top lights the full length of the house, and 2 feet wide to open.

**CONSTRUCTING GREENHOUSE (A Seven-years Subscriber).**—You show in the elevation a window above that of the greenhouse roof, which is unfortunate, as the height at the back shown in the section is only 8 feet; the height of the front, as also represented in the section, is 5 feet 6 inches, giving in 10 feet 10 inches width an incline of but 2 feet 6 inches, which is much too flat. The fall should not be less than 1 foot in 8 of width, which would make the height of the back wall, or the greenhouse at that part, 9 feet, and we should have it 10 feet, calculating externally. One-half of the front lights should be made to open, and a width of lights along the top the whole length, with 18 inches clear space for ventilation. In other respects the arrangements appear good. In the matter of heating you will need a stove boiler. The pipe chimney you propose will be much too large, but the crifice of that of the boiler will determine the diameter of the smoke pipe. You will require a 2-inch flow and return pipe along the two sides and one end, which will be sufficient to give you safety from frost. An open hot-water cistern would not answer at the point marked on the plan, but there is no objection to it if it have a proper fitting iron lid.

**DESTROYING AMERICAN BLIGHT (S. S.).**—Dress the trees with paraffin oil, applying with a brush. It never fails. "S. S." asks if the Rev. W. F. Radcliffe will give the proportions of the lime and salt and water he advises in the Journal for 22nd of July last.

**DRIVING WORMS FROM POTS (Idem).**—There is nothing we know so safe or so effectual as lime water, which there is no difficulty in procuring, as lime had in an unslacked state will keep in a dry place for a considerable time, we having some now as good as when first had, over two years ago.

**NAMES OF FRUITS (H. Mobbs).**—1, Duchesse d'Angoulême; 2, Winter Nells; 3, Margil. (J. Wilson).—Blenheim Pippin. (R. W., Burleigh).—Vernam. (E. M. Stone).—143 to 144, Beurre d'Arcueille; 151, 152, 153, Castille; 97, Josephine de Malines; 177, Passe Colmar; 184, Vicar of Winkfield; 275, Beurre d'El. (Dr. Mackenzie).—Duchesse d'Angoulême.

**NAMES OF PLANTS (John Brown).**—Heterocentron roseum; 2, Cheilanthes hirta; 5, Nephrodium sp.; 6, Nephrodium molle; 7, Asplenium Ceterach; 10, Gymnogramma L'Hermierii; No number, Pteris arguta. (W. W. A.).—2, Tridacantha discolor; 3, Habrothamnus fasciculatus; 4, Selaginella Martensii; 5, Selaginella Kranziana; 6, Adiantum cuneatum. (J. F. C.).—1, Asplenium lineatum var.; 2, Nephrodium decompositum, var. glabellum.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### ALL IN, OR ALL OUT, BEFORE JUDGING.

We have been asked on many occasions to write a few lines on this subject; we have, however, refrained from doing so in consequence of the conflicting opinions which seem to exist about it. The practice, doubtless, is carried on much more in the northern than in other counties. We allude, of course, to the permission which some societies grant to exhibitors or their representatives of penning their own birds. We have for some time been thinking that the custom is in danger of being much abused, and the events of the last two or three weeks make us feel more certain of the fact. We know it wants desperate pluck to forbid an exhibitor who has brought his birds two or three hundred miles from entering the portals of the show room, where he wants to see his birds properly penned; but we are convinced that those societies which bravely determine not to budge from their rules in the end gain the most confidence from exhibitors. Nearly every schedule has the words "No one will be admitted except those actually engaged in the arrangements;" then, after the people have been admitted contrary to this rule, if someone should chance to ask why the rule had been broken, the reply would often be given that the persons so admitted, being engaged in penning their birds, were engaged in the arrangements. This, however, all must agree, is a loose way of looking at rules, and sounds rather like quibbling. But so it is; and we believe that some societies, relying on the help of these men coming with their birds, do not consequently engage a full complement of servants. Anyhow we know of an exhibition where there was literally not one man engaged to help to pen the birds, for the secretary was working single-handed and without a committee, and we verily believe that had not we ourselves, who had come 150 miles to attend the show, with the valuable aid of a true fancier living in the neighbourhood, not given a helping hand the baskets could never have been opened before the Judges came round. Now if a show cannot afford a sufficient staff of working men the exhibition should not be held at all, for help from outsiders should never be relied upon or countenanced.

We do not wish to imply that the people who gain entrance would do any harm to the birds—very far from it, for we believe that the number of people who would do such a thing must be and is very small. Still the system is wrong in giving to non-

attending exhibitors the possibility of suspecting that foul play may be used, and that they have not the same chance of being able to see to their birds' welfare, and to their being smartened-up before placed in their pens. Now this is all true, and we would strongly advise all societies who insert this rule into their schedules to be more careful in observing it. Of course the rule is optional, consequently those committees who like to let in exhibitors and others before the judging can do so in all fairness by not inserting the rule at all, and then the fanciers could please themselves about sending or not. But to those who do think well to use such a rule let it, we say, in future be more strictly kept. Among many other societies, Aylesbury, Bristol, and Dorchester keep this regulation, we believe, to the letter, and yet we never heard they lost entries from it. So far from such being the case, we know of some who at inconvenience support these exhibitions for the very reason that they do observe so firmly this rule, and keep out all who are not the officers of the show. We are quite certain that if the regulation was impartially adhered to no one would grumble; but to admit some favoured friend and keep out a stranger is very bad management. Let it be stated in the schedule that anyone may pen their birds that likes to bring them, provided they keep to the other rules of the show, which could then be drawn-up at the discretion of the committee; or, on the other hand, let it be stated that no one will be able to gain entrance; so that it may be known that when a rule is made it will be carried out, and then one species of grumbling will be knocked on the head. As the rule is now used it fails utterly, for we ourselves have personally attended a show and taken our birds, gaining admission to the building, and then on the next occasion been refused, while the rules stood the same in both years; and not at one show only, but at show after show and year after year is this the case. If only the non-attending exhibitor knew the rule would be enforced he would send his birds with a much happier heart, supposing, of course, the regulation existed, for if it did not he should have found that out before entering. And again, how often it would prevent an exhibitor coming a long distance, to find only when he reached the show that he could not get in for perhaps twenty-four hours or more.

We do not enter into the late cases of grievance, for it would do no one any good, but we do feel that if the poultry world could only put more implicit confidence in the officers of our exhibitions it would be so much better. They must not be too ready to suspect and impute base designs on the gentlemen who so often at such great expense and labour get up and manage these shows, for we all know that without them the poultry fancy would soon begin to wane. It is the friendly rivalry and competition at these shows which cements so closely our vast poultry fabric. The committees, however, should never give a vestige of suspicion by allowing any one rule being disregarded; and as this one to which we have alluded is itself so important and so frequently broken, we hope managers will henceforth try to put things on a fairer and more straightforward basis. This they can do by making their rules and regulations as they like, but when it comes to the case of admitting anyone before the judging, let no favour be shown to anyone. Let the point be clearly known, so that we may know a society by the fact of its regulations being impartially observed. So that regarding the question we have been writing about, it may always be a case of all in, or all out, before the judging.—W.

### GUILDFORD POULTRY SHOW.

This Show grows apace, and instead of being relegated to queer little places, now fills a large drill-hall, so far as the walls are concerned, the centre of the hall being devoted to roots. For many years we have been the advocates of poultry forming part of every agricultural meeting, especially when they are held in connection with the approaching Christmas markets. If, however, we advocate this as a general rule, it applies with greater force to Surrey. This county was always the home of the best poultry, and to this day to speak of a fowl as a Surrey fowl is to give the assurance that it is one of the best the country affords. It has long been said poultry must at last receive the attention it deserves. We were never more convinced of this than we were when, going to this Show on Tuesday last, we saw the numbers of Geese and Turkeys that were shown. We shall have to speak of them later. Poultry must some day play a more important part in feeding the nation than it does now, and some of the hundreds of thousands sent abroad annually must be kept at home. This cannot be done by the mass of amateurs. With few exceptions they have not the space or the conveniences for rearing chickens. That which can be attained only by a great outlay by amateurs, is already provided gratuitously for those who are engaged in agricultural pursuits. They have space, shelter, and food all available in a farmyard. Good judges have said if as much attention were paid to poultry as to sheep they would pay as well, and we believe it.

With these thoughts running in our minds we were glad to

begin with thirty-three pens of *Dorkings*, and to find the cup and other prizes went to Dorking; thus showing, that although it may be a bootless errand to go to Siltton for cheese, the same cannot be said of Dorking. This Show is remarkable for a good class of Cuckoo Dorkings, the present was no exception. The White Dorkings were also excellent. Had not the cup for the best pen in the four first classes been given to the Coloured, it would have gone to the Whites. They were very superior birds. There is, however, one remark we must make, and that is the prevalence of spurs on the outer part of the leg. This is a recent complaint, but it is on the increase. This has never been a *Cochin* show, the present was no exception. There was not a pen of Buff. There were some good Whites, and a young pen of Grouse that will improve with age. There was a good display of *Brahmas*, but we suppose some of the Darks had been bred purposely for vulture hooks. They were more than exaggerated, reaching nearly to the ground. The Lights were much better than the Darks; accounted for by Mr. Pares having formerly lived in the neighbourhood, and showing what may be done by disseminating good birds. The *Spanish* were not numerous; some of them were good, but these and the *Cochins* were the weak classes. The show of *Game* was excellent, a cup given for the best pen in nine classes was taken by a pair of Brown Reds. There were few *Houdans* and *Orpingtons*; they were, however, good, especially the latter. The rule of larger shows was observed here. The Golden-pencilled were the best of all the *Hamburgs*. There were excellent specimens. The show of *Game Bantams* was good.

Rouen and Aylesbury Ducks met in competition. The Rouens were the heavier, but the Aylesburies were worthy of great praise. We have never seen better-bred or better-shaped Ducks. We here made the acquaintance of a novelty. We have known hen-cooks for years, but we here saw that which we must call a Duck-drake—the plumage so far as the body was concerned, and the voice of a Duck; the curly tail, and the green head and neck of the drake. As when similar anomalies are met with in Pheasants, the colours were dull as compared with the male. There were sixteen pens of first-rate *Turkeys*, we can vouch for their breed and their condition, their weights will speak for themselves. A cock and hen were shown in each class, and the weights were for old birds 48 lbs., 47 lbs., and 44 lbs.; for birds of the year 35 lbs., 33½ lbs., and 32½ lbs. There were two classes of *Geese*. Two birds constituted a pen, and the prizetakers weighed 42½ lbs., 42, and 37 lbs. Among the young ones, 32 lbs., 31 lbs., and 30½ lbs.; of old a poultry show was always held under the auspices of "a society for the improvement of domestic poultry." In most instances it has signally and totally failed. Birds have been bred and sold for large prices for exhibition, but the supply of table poultry in most places has become smaller and worse. Let the *Geese* and *Turkeys* speak for the success that has attended Guildford. It is more than likely these birds eat no more than their predecessors did in the days when a Goose or hen Turkey of 9 lbs. was well spoken of, and anything above that weight was an exploit. To those who, travelling from Woking to Guildford, and notice the hundreds of *Geese* by the side of the small stream, and others "seeking their fortunes" on the common, it becomes an interesting question to ask one's self if, owing to the encouragement given by these societies, every Goose is 8 lbs. heavier than its fellow was twelve years ago, and if the same may be said of *Turkeys*, what is the gain in the actual amount of food available for the people? It is in this respect that one of these shows does more practical good than twenty of those held only for the purpose of showing birds bred to a point or a feather which are attained at the cost of more valuable properties.

Mr. Bailly was the Judge. We published the awards last week.

### WOOLWICH, PLUMSTEAD, AND CHARLTON POULTRY SHOW.

This was held in the Alexandra Hall, Woolwich, and was creditable to the exhibitors and supporters, who are chiefly working men, who started and sustain the Society from the pure love of the fancy.

The exhibitors were mostly dwellers in the neighbourhood, although Norfolk and Faversham, &c., put in an appearance with success. The pens were arranged by Mr. Billet, and from the light only coming from the roof, and the pens being in two tiers, the lower pens were in darkness, which must have been perplexing to the Arbitrator; but with the number of pens—nearly two hundred—we do not think this could be avoided. A larger room will be required with the increasing progress of the Society.

*Brahmas*, *Darks*, headed the list, followed by *Lights*. Some good birds were shown, but in many cases (being in pairs), two good birds were not in same pen, and matching was somewhat defective. This, in fact, was the case in many classes, causing much trouble in making the awards. The classes also were

open and for members, thus causing double awards. We think it would be better to keep these classes to themselves if possible, as was done with younger birds. The *Cochin* prize was taken by a grand old bird, we believe a former winner at Croydon. The white on his deaf ears should not have been, but it would have been hard to have ruled him out for this. In the *Dorking* class there was the best specimen of outside spurs we have seen for some time. *Spanish* was a fair class. The *French* varieties better, but then *Dring* headed the list; we rather fancied his *Houdans*, but they were not well matched, which lost them second place. The first-prize *Brown Red Game* good, and a good pair not dubbed. *Hamburgs* were not too good, and the breast of the Pencilled prize hen much too light, but the cock was good. *Bantams*, all varieties, were chiefly *Game*. We hear there was some grumbling over the awards in this class, a *Crystal Palace* winner and a *Leeds* winner not holding their former position. We certainly thought the commended *Duckwing* cock the best in the class, but not so the pullets, and as the awards were for pairs we think that must have been the difficulty. *Game Bantam* exhibitors should remember that the *Bantam* drooping wing should not be seen: this was the general fault. In the distinct varieties there were some fine *Malays*; we liked the carriage of the highly commended *Malays* better than the other, but the white on tail, &c., was a defect. In *Selling* classes good *Black Cochins* were first, *Houdans* second, a good pen of *Black Hamburg* third, and *Spanish* fourth. There were some good birds shown in the classes for members here this year, showing the spirit at least is willing.

In *Pigeons*, *Antwerps* headed the list with sixteen pens. The Judge highly commended the whole class, his awards being chiefly to the homing type of bird rather than the show. There was nothing very striking in the rest of the *Pigeon* classes, but a pair of *Archangels* took first in the *Variety* class. We congratulate *Woolwich* on its second Exhibition, and hope that *Ashford Show*, the *Dog Show*, and other shows have not taken away its visitors. The awards were made by Col. F. C. Hassard, C.B.

#### BARTON-ON-HUMBER SHOW OF POULTRY, &c.

THIS Show took place in the Volunteer Hall on the 8th inst. There were upwards of 700 exhibits, an increase of 200 on last year's exhibition. The poultry were over 257 pens, the specimens in both the *Game* classes and *Bantams* being especially good. There were 162 entries of *Pigeons*, the specimens possessing more than ordinary merit. The arrangement of the pens was a great drawback to the Show, they were placed in four tiers from floor to ceiling, and numbered from bottom to top, making it almost impossible to judge fairly, as the birds were placed in such inequality of position, and it also made it very difficult for the public to view them, requiring a ladder to see the top birds properly, and to stoop down to see those at the bottom. We were very sorry to see so many birds, both *poultry* and *Pigeons*, arrive too late for competition.

*Game*, *Black Red* or any other *Red*.—Mr. Adams, first prize and cup in addition for the best pen of *Game*, with a good pen of *Brown Reds*. We should like the cock bird, none the less were he lighter-coloured in his hackle. We do like the lemon shade in a *Brown Red*. We very much liked Mr. Glassby's second-prize pen of *Black Reds*. *Game*, any other variety.—Mr. Waters first, *Duckwings*, faultless in colour and good in style. Mr. Adams second, with a good pen of *Duckwings*. *Single Game* hens.—Mr. Adams first, with a *Duckwing*. Mr. Waters second, *Brown Red*, a gem, the only fault that we could find with her being a little bronze on her wing flights. *Single Game* cocks.—Mr. Adams first, with a first-class *Duckwing*. Mr. Waters second, *Brown Red*. The third was also a *Duckwing*. *Game Bantams*, *Black* or *Brown Red*.—First, *Dawson*, *Black Red*, a grand pen, but the cockerel very much out of condition. Second and third also *Black Reds*. Two very good pens. The whole class of seventeen pens were of more than average merit. Any other variety.—First and second, *Newbitt*, with *Piles* and *Duckwings*, very stylish; and *Dawson* third. *Bantams*, any variety but *Game*.—First were *Blacks*; second *Gold-laced*; third *Silver-laced*. *Bantam* cock, any variety.—First, and in addition to cup, for the best pen in the Show, was properly awarded to Mr. Stretch's *Black Red Game Bantam*. This bird was as near perfection in colour and style as we ever saw. *Bantam* hens.—The three prizes were awarded to three *Game*. Very good birds. *Spanish*.—Only three pens; with the exception of the first-prize birds only a poor lot. *Dorkings*.—Eight pens of moderate birds. *Brahmas*, *Dark*.—Six pens. First-prize pen contained a very good cock, the hen only moderate. The second and third were average birds. *Light*.—Seven pens, four of which were not for competition. A second prize was only given. *Cochins*.—First, *Spencer*, contained a very good hen. All the three prizes went to *Buff* birds. *Hamburgs*.—With the exception of the *Black Hamburgs*, were a poor lot. *Gold* and *Silver-pencilled*.—First, *Silver*; second, *Gold*. Any other variety.—First and second, *Blacks*; third, *Golden*. *French*.—A good class. The prizes

were all taken by *Crèves*. Any other variety.—The first was awarded to a grand pen of *Golden Polands*; second, *Malays*; third, *Golden Polands*. *Selling* class.—Twenty-five pens, contained some good and cheap birds. The first, a very good pen of *Black Hamburgs*. Second, a nice pen of *Light Brahmas* that must have taken first in their own class had they been entered. Third, a nice pen of *Black Spanish*. Birds hatched in 1875.—Twenty-one pens. First a grand pen of *Brown Red* chickens of great promise. Second, nice *Buff Cochins*. Third, a grand pen of *Light Brahmas*. *Guinea Fowls*.—Four pens of nice birds. The *Ducks* were of average merit. Nine pens *Bouen*, and nine pens *Aylesburys*. In *Ducks*, any other variety, the first and second prizes were taken by Messrs. A. & W. H. Sylvester with their well-known fancy *Ducks*. Third, a nice pen of *East Indians*. *Goose* or *Gander*.—Seven pens. The first a good *Grey*.

We cannot report who won the point cup in poultry. Mr. Waters counting forty points, and Mr. Adams thirty-seven points, but Mr. Adams taking the cup for *Game* as well, it was thought by some that it ought to count, others thought not, as in the schedule of prizes it was not named as counting.

*Pigeons*.—The cup for the best bird in the Show was won by Mr. Jas. Baker, *Spring Grove*, *Kew Bridge*, *London*, with his grand little *Almond* cock, if we mistake not the cup-winner at the *Palace*. The same gentleman carrying off also the point cup. *Pouters*.—First, a grand *Blue*, narrow in girth, good in style, and well marked. Second and third, *Blues*. *Carriers*.—First, a good *Black*. Second, a good *Black* also, but showed badly, would not show up, crouching in the corner of the pen. Second a good *Dun*. *Barbs*.—A really good *Black*; second, *Black*; third, *Red*. *Owls*.—First, a magnificent *Blue English*. *Turbits*.—First, *Silver*; second, *Blue*; third, *Red*. A class of great merit. Sixteen pens. *Jacobins*.—First, second, and third, *Baker*. All *Red*. *Tumblers*.—First and cup, a splendid little *Almond*. We could find no fault with him, unless it was that he might have had a little broader skull. Second, a wonderful good *Almond* hen; and third, one of the best *Kites* that we have seen for years. Mr. Adams's grand *Almond* cock had to be put off with highly commended. £20 was offered and refused for this bird. *Fantails*.—Mr. Brown first, with a good *White* bird that showed to great advantage, facing you, and carrying a good tail well. Second and third, *Baker*, *Blue* and *White*. *Antwerps*.—First and second, *Short-faced Silver Duns*. Third, *Long-faced Blue Chequered*. Mr. Gamon sent two good pens which would have stood first and second had they not been penned after judging. We saw them penned on the morning after the birds were judged. *Dragoons*.—First, a grand *Blue*, just the bird that we know Mr. Cannan wants in a *Dragoon*. A straight, stout, box beak, from back of head to beak end straight, no drop as in the *Carrier*, a great fault in most of the heavy birds, not much wattle on beak or eye, a good neck, good shoulders, strong in butt of wing, wing not too long as to touch the ground, broad flight feathers, each feather when wing opened out lapping a little over the other, standing well up on the legs, showing the thighs well, looking as if he was ready to dart away if at liberty, hard feather and all of a piece. We know that he contends that the *Dragoon* as well as the *Antwerp* are flying birds, and that to a great extent he judges them for this. We think that he is right. It is high time that exhibitors knew what style of bird to send. We have watched Mr. Cannan's awards, and where it is known that he will judge it will be of no use sending the heavy birds that win with some judges. Second and third were *White* and *Yellow*. Any other variety.—First, *Russian Trumpeter*; second, a really good *Black Nun*; third, *Trumpeter*.

#### EDINBURGH CHRISTMAS CLUB POULTRY SHOW.

THIS important Show was held on December 8th, 9th, and 10th, in the Grass Market, *Edinburgh*; the entries numbered over one thousand, and the quality was first-rate, but the managers have still much to learn as to arrangements; the place was too small, and tier on tier of pens met the eye. Certainly no breed was favoured. *Cochin* and *Bantam* cocks shared equally with others; the top rows of pens over 5 feet from the ground, we should think, and no fancier needs to be told *Cochins* don't do that height. Again, the dishes for water were in many instances large brown basins, big enough for the birds to stand in, and several birds had apparently taken the opportunity to render themselves unfit for exhibition this season, and so get clear of the, to them, show nuisance.

*Scotch Greys* headed the list, and a fine lot they were. The first-prize cockerel was a good one, but too *Cuckoo-Dorking*-like in shape. The best in the class was Mr. Girdwood's, a clearly marked and stylish cockerel. In cocks the same fault (*Dorking*-shaped) was noticeable, while the pullets and hens were grand classes. The first old hen the best *Scotch Grey* in the Show. *Dorkings* were, as they always are, good at this Show, and the judging was mostly good. Mr. Robb's old bird is a well-known

**SELLING CLASS**.—1 and special, W. F. Clarke, Nottingham. 2, H. Yandle; 3, M. Leno. *Ac*, E. Banton, E. W. Webb.

#### RABBITS.

### DORKING POULTRY SHOW.

THE sixteenth annual Show was held on the 16th inst. The object of the Society seems to be exclusively for the encouragement of breeders of Dorkings, there being sixteen classes devoted to them and only five to other varieties. In four of the Dorking classes and a Selling class the competition was open to all England; the remaining classes were confined to the town and immediate vicinity of Dorking. We have often spoken in favour of local shows as being an inducement to amateur exhibitors, but we fear that a show so thoroughly exclusive must tend to give a wrong impression of the qualifications of prize-winners as many birds placed in the prize list there would have passed unnoticed in our smallest shows. We, therefore, recommend the Society to extend the competition to twenty miles instead of twelve—or why not to all Surrey? as we feel sure there would be a marked improvement in the birds exhibited.

In the class of old birds the competition was very close between Messrs. Burnell and Parlett. We preferred the cock in the pen exhibited by Mr. Parlett, as he was shorter in the leg and better in shape than the winner, but he was mated with a hen very crooked in the breast, which, doubtless, turned the scales; in other points we considered her very good. The others were far behind and the third prize withheld. In the cockerel and pullet class Mr. Burnell was first and second with very grand birds, but we thought the cup should have been given for the pen of young birds in preference to the old. In the cockerel and pairs of pullets Mr. Burnell was an easy winner, his pullets being a charming pair and excellent matched. In the local class for coloured cock and hen over one year Mr. G. Ellis was first, and obtained the cup with a fair cock matched with a large hen, a little white in the lobe, other wise good. In the remaining pens of the Coloured class there were no birds of any pretension. Blue-speckled Cuckoo Dorking.—In this class Mr. Griffin was first (cup) with a really good pen. We were extremely pleased with the hens, and they were quickly claimed for £5. Mr. Young was first in the class for pairs of pullets or hens with a beautiful pair of hens sound in colour, well marked, and nicely matched. Whites were a moderate lot, with the exception of a nice pen exhibited by Mr. Mew. In the Game class we saw nothing worthy of notice. The Ducks, Geese, and Turkeys were a very creditable collection to a show of such dimensions.

The Committee and officers appeared to thoroughly understand their business, and we feel sure they would be equal to an exhibition on a larger scale.

**DORKINGS**.—*Coloured*.—Cup, T. C. Burnell, Micheldever. 2, F. Parlett Chelmsford. *Chickens*.—1 and 2, T. C. Burnell. 3, G. Ellis, Gadbrook, Reigate. *Ac*, J. Ivery & Son.

JUDGES.—Poultry and Pigeons: Messrs. Teebay & Dixon.  
Canaries: H. Thirle.

### LIVERPOOL NATIONAL COLUMBIAN SOCIETY'S SHOW.

This was held at Messrs. Lucas's Repository, Great Charlotte  
Street, Liverpool, on the 15th and 16th inst. The awards were  
as follows:—

POULTERS.—Blue pied.—Cock.—1, J. Guthrie. 2 and 3, Rev. W. C. Bullen,  
Liverpool. 4. J. E. Spence, Broughty Ferry. Ac. J. Gardner. Hen.—1, 2, and  
3, Rev. W. C. Bullen. 4. J. Guthrie.  
POULTERS.—Black pied.—Cock.—1 and 2, Rev. W. C. Bullen. 3. J. Guthrie.  
Kerham. 4. H. Vardon, Liverpool. Hen.—1, Rev. W. C.  
Bullen. 2. J. Guthrie.  
POULTERS.—Red or Yellow pied.—Cock.—1, J. Guthrie. Hen.—1, J. Guthrie.  
2. W. J. Warhurst.  
POULTERS.—White.—Cock.—1, Rev. W. C. Bullen. 2. W. J. Warhurst, Staley-  
bridge. 3. W. Lees, Oldham. Hen.—1, J. E. Spence. 2. H. Simpson, Spalding.  
3. Rev. W. C. Bullen. Ac. H. Vardon.  
POULTERS.—Any other colour or marking.—Cock.—1 and 2, J. Guthrie. 3.  
J. E. Cryer, Southport. 4. W. J. Warhurst. Hen.—1, J. Guthrie. 2. H.  
Vardon.  
POULTERS.—Any colour or marking.—Young Cock or Hen.—1 and 2, J. Guthrie.  
3. H. Simpson.  
CARRIERS.—Black.—Cock.—1, 2, and 3, E. C. Stretch, Ormskirk. 4. S. Drons-  
field, Werneth. Hen.—1, T. Hewitt, Knutsford. 2. H. Vardon, 3. E. C. Stretch,  
4. J. E. Cryer. 5. C. E. Duckworth, Liverpool. Ac. W. Lees.  
CARRIERS.—Dun.—Cock.—1, E. C. Stretch. 2. E. C. Stretch.  
3. H. Simpson. Hen.—1, J. Stanley, Blackburn. 2. E. C. Stretch. 3. A.  
McKenzie, Liverpool. Ac. W. Sefton. 4. W. Lees.  
CARRIERS.—Any other colour.—Cock.—1, 2, and 3, E. C. Stretch. 4. W.  
Sefton. 5. F. Graham. Hen.—1, J. Guthrie. 2 and 3, E. C. Stretch.  
CARRIERS.—Black.—Young Cock or Hen.—1, H. Simpson. 2. C. E. Duckworth.  
3. S. Dronsfield. Hen.—1, E. C. Stretch.  
CARRIERS.—Dun.—Young Cock or Hen.—1 and 2, J. James, Bath. 3. E. C.  
Stretch. 4. H. Simpson. Ac. T. Hewitt. 5. J. E. Cryer.  
CARRIERS.—Any other colour.—Young Cock or Hen.—1 and 2, E. C. Stretch.  
3. A. McKenzie. Hen.—1, T. Hewitt. 2. H. Vardon. 3. J. E. Cryer.  
BARR.—Black.—Cock.—1, J. Stanley. 2. A. Sharples, Wootton. Hen.—1, J. Stanley.  
2. W. J. Warhurst. 3. J. E. Cryer. 4. S. Dronsfield.  
BARR.—Dun.—Cock.—1 and 2, J. E. Cryer. Hen.—1 and 2, J. Stanley.  
BARR.—Red or Yellow.—Cock.—1, S. Dronsfield. 2. A. Sharples, Manchester.  
3. W. Lees. Hen.—1, J. E. Cryer. 2. J. Stanley. Hen.—1, S. Dronsfield. 2. A.  
Sharples. 3. A. Sharples.  
BARR.—Any other colour.—Cock or Hen.—1, 2, and 3, J. E. Cryer.  
BARR.—Black or Dun.—Young Cock or Hen.—1, J. Stanley. 2 and 3, J. H.  
Cryer. Hen.—1, J. Stanley, J. H. Cryer. Ac. J. Stanley, J. H. Cryer, F. H. Jones.  
BARR.—Any other colour.—Young Cock or Hen.—1 and 2, F. H. Jones. 3. J.  
Stanley. Ac. and 4, S. Dronsfield.

Ac, J. Guthrie. Ac, O. A. Pearson.

SELLING CLASS.—Young Cock or Hen—1 and Ac, C. A. Pearson. s, J. Guthrie.

s and s, A. McKennie.

The Judges were Mr. F. Esquilant, Brixton, London; Mr. J.

Hawley, Gillingham, Bradford; Mr. H. Allsop, Birmingham.

## MONTROSE POULTRY AND PIGEON SHOW.

THIS Exhibition was held on the 17th and 18th inst. in the Corn Exchange. The awards were as follows:—

DORKINGS.—1, A. Matheson. s, Mrs. J. Smart.

SHIRAZ.—1, special, and c, Mrs. W. Stevens. s, J. Ogg. s, D. KMA. Ac,

J. Milne, Mrs. W. Stevens.

COCKS.—1 and special, Mrs. J. Davidson. s, A. Bowie. s, Mrs. A. G.

Duncan. s, Mrs. C. B. Taylor. Ac, A. Burnett. Mrs. A. G. Duncan, Mrs.

W. Stevens, Mrs. C. B. Taylor. Ac, A. Bowie. c, Mrs. J. Davidson, Mrs. W.

Stevens.

BRAMMAS.—1 and s, A. Burnett. s, W. G. Duncan. Ac, A. Fullick. c, A.

Burnett. A. Fullick, Mrs. W. Stevens.

GAME.—1 and special, J. Selmond. s, R. J. Nicoll. Ac, W. Nicoll. c, T. W.

Mitchell.

POLANDS.—1, s, and special, J. Taylor. s, Mrs. C. B. Taylor. s, W. H.

Far. Ac, J. Matthew. c, A. Duthie, Mrs. C. B. Taylor.

HAMBOURGERS.—Golden-spangled.—1, J. Taylor. s, W. L. Blyth. s, J.

Milne. c, J. Ireland. Silver-spangled.—1, W. B. Park. s and s, J. M.

Campbell. s, A. Baxter. Ac, G. Beattie, G. Campbell. Gold or Silver-pen-

cilled.—and special, W. B. Park. s, J. Ogg. s, J. Taylor. c, W. Maris.

HOUBANDS.—1, A. C. Mart. s, M. Todd. s, Mrs. C. B. Taylor.

ANY OTHER DISTINCT BREED.—1, W. B. Park. s, J. Marshall. s, A. C.

Mart. c, P. Macdonald.

GAME BANTAMS.—1 and special, B. Brownlie. s, W. Ballie. s, J. D.

Donald. s, T. Harrower. Ac, J. Strachan, D. Ormond, A. Frew, J. Dalg.

c, J. Strachan, Mrs. C. B. Taylor, J. Grive.

BANTAMS.—Sabbath.—1, B. P. Frew. s and c, J. Dallas. s, J. Taylor.

Any other variety.—1, s, and special, R. H. Ashton. Members' Special and

s, J. D. Donald. Ac, D. Duncan, J. Taylor. c, R. C. Frew, J. D. Donald.

SELLING CLASS.—Cock—1, A. Duthie. s, G. B. Dick. s, Mrs. W. Stevens.

Ac, A. Burnett. Mrs. W. Stevens. Ac, Mrs. J. Davidson, J. D. Donald, Mrs.

W. Stevens, J. Milne. c, P. Stewart, J. Taylor, F. McDonald. Hen—1, Mrs.

C. B. Taylor. s, B. Rawlings. s, A. Burnett. Ac, A. C. Mart, F. McDonald,

Mrs. W. Stevens.

DOCKS.—Dylebury.—1, s, and s, A. Burnett. Any other variety.—1, J.

Fowler. s, Mrs. W. Nicoll. s, R. Robertson. c, M. Garland.

GREEN.—1, J. Orell. s, B. Rawlings. s, M. Garland.

TURKEYS.—1, A. Bowie. s, M. Garland. s, J. W. Davidson. Ac, Mrs. C. B.

Taylor, J. W. Davidson.

#### PIGEONS.

FOURSON.—Cock—1 and s, J. Mitchell. s, J. E. Spence. s, J. Day. Ac,

J. Ove. c, T. L. Johnston. Hen—1, s, and special, J. Mitchell. s, T.

Mullion. c, T. L. Johnston. Young—1 and s, J. Mitchell. s and s, J.

Day. Ac, T. L. Johnston.

CARRIERS.—Cock or Hen—1 and s, J. Lamont, jun. s, A. Smith. Ac, J.

Taylor.

BARRS.—1, J. E. Spence. s, A. Burnett. s, A. Dunbar. Ac, R. J. Wilson,

A. Burnett.

TUMBLERS.—Short-faced.—1, s, and special, D. Braah. s, J. E. Spence.

Ac, J. Glenday. Common House.—1, W. & B. Davidson. s, J. W. Davidson,

s, J. Shield. Ac, B. Ross.

FANTAILS.—1, Mrs. A. G. Duncan. s, A. Croable. s, A. Smith.

JACOBINS.—1 and s, W. & B. Davidson. s, J. Matthew.

TRUMPETERS.—1, J. M. Rodgers. s, J. McDonald. s, T. L. Johnston.

TURBETS.—1 and special, A. Croable. s, R. J. Wilson. s, D. Feltie. Ac, H.

Colston. c, J. Taylor.

OWLS.—English.—1, s, and Members' Special, Ac, c, W. & B. Davidson.

s, J. Lamont, jun.

NUNS.—1 and s, J. Lamont. s, A. Duthie. Ac, J. Taylor. c, J. Matthew.

**BEST AND MOST VARIED COLLECTION OF BIRDS.**—1, W. Cruickshank. 2, W. Robertson.  
**RABBITS.**—1, Mrs. Roberts. 2, A. Frew. 3, G. Douglas.

The Judges were for Poultry Mr. Hutton; Pigeons, Messrs. Huie and Ure.

### SWANSEA SHOW OF POULTRY, &c.

ONE of the best, if not the very best, Shows ever held in Wales was that at Swansea in the covered market on the 9th instant.

**Dorkings** headed the list, the whole being Dark Greys and an excellent lot, the cup being awarded to old birds. *Spanish* were very good, but not numerous; but of *Game* there were great numbers. The Black Reds were a fair lot, but some of the hens were so much overtrimmed round their eyes that there was no alternative but to leave them out. Brown Reds were a better lot than the Black Reds, the cup for *Game* being awarded to a handsome pair of old birds. There were some White *Game*, which, though good of their kind, were not equal to the rest. In Any other colour of *Game* the first were old Duckwings, very good in all points; the second Piles, the cockerel being undubbed; the third also Duckwings. Buff *Cochins* were very good, the shape and style of the winners grand and very close in quality. In the next class first were Partridge chickens, second old Whites, and third nice Blacks. The *Hamburgs* sections were a great success, the winners being very good. The Gold-spangles very good, and a close run, the first hen only turning the scale, and she is a truly grand bird. The cup for Spangles was won by Silvers, the second losing by the cock being scarcely as well spangled on the tail hackle, and a twist in the earlobe. The Pencil cup was won by the Hanley cup pen, a pair of birds that need no comment; the second in this class contained a grand pullet; but with the exception of the two first the Silver-pencils were not good. Black *Hamburgs* were very good as regards the winners. *Polish* were both numerous and good, the cup for these two classes going to a grand pen of Silver *Polish*. Dark *Brahmas* were good in the old but only moderate in the young class, but the Light variety were really grand in all respects. *Houdans* were a fair class, the winners good, and with fair good combs. Brown *Leghorns* a fair lot, while the *La Flèche* and *Crève-Cœur* were very good, the cup won by the first *La Flèche*. In the Variety class Red Malays were first, Sultans second, and Minorcas third. *Game Bantams* were not good as a class, but the winners were very good Black Reds, the cup for Bantams being awarded here. In the Variety of Bantams the winners were Blacks. *Game cockerels* were a large but not a good class. The first-and-cup was a handsome Duckwing, the second an undubbed Pile, and third a Brown Red, rather thin, but of promising quality. *Game pullets* were a fair lot. The first Brown Reds, second and third Duckwing; but the best of all was a Pile too late for competition.

*Ducks* were pretty good in all classes. *Geese* and *Turkeys* very large and well shown.

There was a point cup for *Pigeons*, which was won by Mr. Spencer of Hereford. Carriers were exceedingly good in both classes. In cocks, first was a Dun and the others Black. The winning hens Dun. Pouters were of fair quality, but not as large as is desirable, Whites winning all, except the first in hens, which was a Blue. Of Almonds only two pairs. In the other Tumblers the first were Kites, second Yellow Balas, and third Blue Beards. Antwerps were only good as regards the

winners. The winning Jacobins very good. First Reds, second Yellows, and third Reds. In Fantails were some good birds, but these were shown well in pairs. Turbits a good class, and an extra prize given. First and second Blue, extra second Red, and third Blacks. Owls, which were mostly Whites, were the best class in the Show; the first-prize pair very good in head. Nuns were very good, as also the Magpies, but the Dragoon—only a moderate lot. Mr. E. Hutton, Pudsey, Leeds, was Judge.

**BEDALE POULTRY SHOW.**—This was held on the 14th inst. There was a good show of Poultry, Pigeons, Rabbits, &c. The entries exceeded last year by 108. The quality of the birds was good in nearly all the classes, and competition close in some of them. The Show was held in the Drill Hall, which was too small for the purpose, and the light was not very good, which made the judging difficult.

### OUR LETTER BOX.

**GRINDING CORN FOR POULTRY (J. H. G.).**—We have been for many years successful breeders and feeders of poultry. Our system has always been to give ground food morning and evening, and whole corn at midday. This keeps running fowls in perfect condition. If it is intended to keep all in more than good condition—i.e., as fit to kill rather more than moderately fat, in the state known as "peckers," we should give none but ground and slaked food, and should feed four times daily. The consumption would be little more than when fed three times, the difference is only in trouble and labour. Economical feeding is to give ground food slaked, either barley-meal or ground oats, morning and evening; whole corn midday. If any amateur will superintend the food three days he will find out the average. This does not increase, rather decreases. It is then easy to fix the consumption. We give the result of many years' close observation. We give no other food. Excepting when there is snow on the ground we always scatter it broadcast. It tends much to health and well-doing if fowls have to search for their food.

**DORKING COCKEREL.**—Mrs. G. Pasley writes to us that her Dorking cockerel won the third prize at the Crystal Palace, and that she still possesses him.

**COCHINS AT SWANSEA.**—The second prize was awarded to Mr. E. S. Woodgate's Whites, and not to Mr. B. Wingfield, as stated last week.

**BEE-KEEPING IN N. SCOTLAND (J. S. Huxley).**—The MS. has not been received.

**FEEDING BEES (Alpha).**—At this season the bees of healthy hives carry out their dead every fine day. Those you find at the entrance of your hives have died by reason of their age and been cast out. Your bees have not yet suffered from want of food, but your way of feeding them is faulty, seeing you find two or three dozen of bees drowned in the trough every time you use it. Bees cannot ascend on smooth surfaces—all deep feeding dishes and cylinders should have their inner surfaces made rough in some way, or be lined with perforated zinc. We do not think your bees will die of want for a few weeks; but to make all safe we advise you to take them into a warm room of your house for a time, and then feed them with warm syrup, confining the bees to their hive of course while in the house. Remember next year to give your bees all they want for the winter in September.

**PRICKLY COMFERT.**—"G. M." asks: "What cultivation and what soil suits it, and if it is suitable food for Alderney cows?" We shall be obliged by anyone answering these questions, for we have no experience to rely upon.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

15th.—Fine all day, but dull and very dark, especially in the afternoon.  
 16th.—Foggy and dark all day, but darker than caused by the fog, which was not very dense.  
 17th.—Foggy, but not so dark as yesterday; fine at times, but rather damp.  
 18th.—Still rather thick; a dull damp day, but no rain.  
 19th.—Rain all the forenoon, very bright at times between 1 and 2 P.M., dull afternoon, but starlit night.  
 20th.—Fine morning but soon clouding over, and rain at noon and in afternoon; windy at night.  
 21st.—Rain in the night, but the finest day though but very little sun. Rain and gale at night.  
 A dark disagreeable week, about 4° warmer than the preceding.—G. J. SYMONS.

### COVENT GARDEN MARKET.—DECEMBER 22.

THE Market is still well supplied with all classes of goods, but there is great difficulty in clearing common samples. Large quantities of St. Michael Pines are now arriving, making a complete drug of the English fruits.

From observations taken near London during forty-three years, the average day temperature of the week is 42.8°; and its night temperature 35.3°.

## A NEW YEAR'S GREETING.

Will you write our new-year's address for us?" How very easily and jauntily these words were written, but how difficult to comply with when one remembers how the same thing has been done in years past by "WILTSHIRE RECTOR" and other friends. At first "I didn't see it," but as I sat meditating on that reply, and watching the glowing coals of a good fire in front of which I was sitting, it seemed to me to savour of cowardice; and as I gazed still further there seemed to me to come up "faces in the fire" which reminded me of things past, and so I deemed it possible by revealing their teachings to say a few words that might be of profit to the many readers of "our Journal," in whose continued prosperity we delight to feel that we all have an interest.

Ah! there is a face that brings me back to some five and forty years, when as yet, save in a youngster's love of "posies," the love of flowers had not been developed—a schoolfellow, who lived near to us in the neighbourhood of Dublin, asking me to come and see his "Uncle Joe" beds of Ranunculus. I went, and was fairly conquered. I have never since then seen beds equal to them, although as yet Mr. Lightbody and others had not tried their hands at hybridising; and from that time forward I became a lover and grower of flowers. Little did he, whose face I see before me, think how much he was doing for me then—how he was starting me on a line which, if it has not brought me unmixed pleasure, has tended to give me much real enjoyment, and has made for me many friends, of whom, indeed, a large number are cherished in memory only, but many, I am thankful to say, still to be greeted. Time rolls on, and now I see another beaming face, fair as are the flowers she gazes on (smile not, I was married at the time), my garden then on top of a cliff overhanging the sea, from whose blasts I could only protect my flowers by erecting a Gorse fence. But, oh! how many pleasant days did that little garden give me, and how readily I forgave the same young damsel when she picked some of my choicest Carnations and Picotees! And now what a change! I am in a small house with a "bricklayer's garden" at that cockney watering-place Ramsgate; but even there the old love will not be daunted, and out of that square piece no larger than an ordinary room I had as many flowers and as much enjoyment as many of my neighbours with places three times the size. And yet once more: A change again, and I see many a face associating itself with dear old Deal, where for nearly twenty years, in a piece of ground forming merely a part of a field, I was enabled to grow so many things that friends sometimes wondered whether my imagination was not larger than my garden. During that time many a friendship was formed which was founded simply on a common love of flowers; amongst them I am proud to reckon the two "venerable fathers" who preside over the destinies of "our Journal." It was

then some fifteen or sixteen years ago that by our common friend John Standish I was introduced to them, and commenced that connection with this Journal which has been to me so full of pleasure and so mixed up with the doings of these last years of my life.

If I have thus far been egotistical it is because I want to give a word of encouragement from my own personal experience. One cannot have lived close upon sixty years without having had a share of those troubles and anxieties for which we are told man is born; and I want to tell my brethren, whether lay or cleric, male or female, professional or amateur, that there is nothing of things essentially connected with this life that has more tended to soothe and solace me than the enjoyments of a garden. When worried with the anxieties of a large parish, or perplexed with those domestic sorrows which we all share, I have often turned to my garden and found in the company of some of my favourite flowers gentle voices speaking to me words of quietness and rest. One's mind can hardly fail to be lifted up at such times to Him who made these very flowers the text of His sermons; and the thought will then come, If He takes care of these will He not take care of me? And to all, whether they be dwellers in town or country, I would say as their best friend, Yourselves cultivate and encourage in those over whom you may have any influence a love of flowers. It can hardly fail to do good, to elevate and refine; and I look upon the increased facilities which have been given to the cultivation of flowers in our huge metropolis as a hopeful sign, tending to give even our roughs something to look upon and think over better than those things in which they can alone see pleasure—better than rat hunts and dog-fighting, and such like brutalising pursuits.

If I turn from these generalities to the more special affairs of our Journal I think we have cause to felicitate ourselves on the fact that it has not only not diminished in interest, but increased. There is not one of the readers of it who, I am sure, is not glad to think that our "most potent, grave, and reverend seigneurs" still wield (not the bâton of command, or the battleaxe of slaughter, but) the pen of friendly criticism and revision. I am not in the secrets of the prisonhouse, but I shall not be far wrong in saying that to their wise and firm use of the pen in cutting out smart (but bitter) sayings, and in toning down the force of expressions of which the writer did not see the danger, we owe a great deal of that kindly feeling which exists amongst the contributors and readers of the Journal. And go where one will, such is its character that the very announcement of a connection with it is sure to be a sufficient passport in horticultural circles. I think we shall the more felicitate ourselves on this when we recollect that one of them has during the year performed an action which I can only compare to that of Quintus Curtius leaping into the gap on the Roman Forum, in accepting the post of Secretary of the Royal Horticultural Society. It was an act of self-devotion, one in which "monkeys' allowance—more kicks than ha'pence," was all he might expect; and we must only hope that he will not meet the fate of that redoubtable

hero of Roman history, but come back safe again from his perilous enterprise.

In that part of the Journal in which I am most interested I think we can fairly say that although time has made changes, and that one after another of those who ministered to our gratification and profit have passed away, yet their places have been filled by no mean successors. We have missed for years the admirable papers of Donald Beaton, R. Fish, W. Keane, and others, but we have still amongst us those to whose contributions we turn with interest, knowing that we shall find sound practical teaching, and neither the fanciful notions of theorists nor the windy pretensions of would-be philosophers. Let not those who pursue one hobby grumble if the paper is not full for them week by week; such persons seem to me for all the world like those passengers in a railway train, who are always growing because it stops at so many small stations, forgetting that the inhabitants of those places have as much interest in the train stopping there as they have in its stopping at the larger towns to which they belong. So let not the Orchid-grower grumble because so much is taken up by Roses, or the Rose-lover growl if other flowers beside the queen come in for their share. No; "share and share alike" must be our motto. Nor is it without its use that the contributors record their failures as well as their successes. The past year has not been an "*annus mirabilis*" with horticulturists. A more unpropitious one they have rarely had to combat with, although it has been a fighting with the elements. Many of our first-rate growers have recorded in our pages the shifts to which they have been put and the difficulties they have had to surmount; and many an owner of a small garden has been considerably cheered by finding, not that he had companions in misfortune, but that which he had to contend with had been experienced by those who had ample means at their command, while their mode of overcoming difficulties suggested to their humbler imitators how they might do the same. And as it has been to the horticulturist so has the last year been to the aparian and poultry fancier; the former has had to mourn over the worst year he has, perhaps, ever known, while the complaints as to losses in the poultry-yards have neither been few nor faint.

And now a word or two as to the future. There is no fear of the interest in horticultural pursuits flagging. The circle of its devotees seems ever widening, and the efforts of those who introduce novelties from distant lands or produce them in our own do not relax; and if this be so we may rest assured that the interest in our Journal will not relax either. Week after week thousands will eagerly welcome its arrival as a messenger of good will. It will come fraught with no sensational tales, no deeds of horror and shame; but full of wise and careful instructions, of wisdom gleaned in the past and encouragement for the future; and while those who have already so much contributed to our enjoyment and its success will still employ their pens on its behalf, I would that many whom I could name, who are quite as capable, would give us the results of their experience and tell us of their triumphs, losses, and failures, for in horticulture, as in many things, "in the multitude of counsellors is wisdom." Their contributions would be readily welcomed by those who rule our destinies, and we should all benefit by them.

Such are a few of the things which have come to my mind as I have thought over my reply to the question put to me from Fleet Street. And now as a last word may I, as one of the oldest contributors to the horticultural side of our Journal, wish to all our friends a happy new year in the enjoyment of their favourites? and as I should never forget that I am something other and better than a writer on horticulture, may I express a hope that they will not forget that everything here, like the flowers they cherish, is but transitory, and that it behoves us all to look forward to the time when we shall have to join those who have "gone before?" And then may it be ours thus to realise in that Paradise of God, of which Eden with its flowers and fruits was but a faint type, that state of blessed rest when we shall no longer sigh over the memories of the past, or look forward with trembling to the unveiling of the future. And so, my gentle readers all, may you enjoy in its highest, noblest, truest sense,

A HAPPY NEW YEAR.

—D., Deal.

FRUITING OF DOUBLE PEACHES.—Mr. Meehan exhibited some branches of Peach in which the young fruit were twos and

threes from one flower. They were from the Chinese double-flowering kind. He remarked that, as is well known, plants with double flowers were rarely fertile. Either the stamens were wholly changed to petals, or the less vital conditions which always accompanied this floral state were unequal to the task of producing perfect pistils. Vitality, however, was more or less affected by external conditions independently of the mere structure of organs, and this was well illustrated by the remarkable fertility of the Peach this season. Usually large numbers of fruit fell without "setting," as it is technically called by orchardists, not because there was any defect in the organs of reproduction, but from lack of vital force to accomplish so much. This season many more had continued than had been known for many years, and the prospect was for an immense crop of fruit. This abounding vitality had evidently extended to the double Peaches, and had influenced the development of the female organs to an unusual extent.—(*Proceedings of the Philadelphia Academy.*)

### REPOTTING AURICULAS.

A CORRESPONDENT ("ALFRED") wishes to know what shall be done in February with Auriculas that are now rooted up to the top of the soil and through the bottom of the pots. Shall they have a shift? and if not, how shall top-dressing be managed without disturbance of the fibres, and shall offsets be then removed or left on till the May potting?

I remark that it is not stated in what sized pots the plants already are. If they have thus filled 4½-inch or 5-inch pots they are in fine order underground, and presumably above also, and I should not meddle with them. A full-sized florist Auricula has room enough in a 5-inch pot to bloom in perfection, and cannot be too well established in that size. It is worse to over-pot than under-pot these plants. What would be the ruin of a Balsam is the delight of an Auricula.

As the collection in question was repotted in May, with compost probably containing ingredients such as old manure and leaf mould that by this time are compressible into a somewhat less compass, it will be found that a firm and broad, but it must not be a sudden pressure, upon the surface soil will make room for the half-inch or so of top-dressing. The soil must not be thus pressed down if wet or newly watered, and care must be taken to see that the drainage is in good working order.

If the plants are large and in pots manifestly small—say about 8 inches—then those that are so rooted as described may have a shift into 4 or 4½-inch pots, and in that case the room for top-dressing can easily be allowed for.

As to removal of offsets, by all means let those be taken off in February, whether rooted or not, that have any neck of their own. Take them off when growth sets in, and disturb the old plant as little as may be. Many rooted offsets can be drawn out by a patient and judicious handling soon learnt, and will soon re-establish themselves although one of their fibres is sacrificed in preference to breaking the ball of earth to find the end of it.

The removal of offsets early in spring is advisable, not merely because they are otherwise apt to draw upon the resources of the old plant, but also because they may be overlaid and drawn by the overlapping parental foliage, and in an insufficiency of light and air become infested with green fly.—F. D. HONNE, *Kirkby Maseard, Ripon.*

### COVERING VINE BORDERS.

I AM not sorry that Mr. Robson has again opened the question of covering or not covering Vine borders. I think gardeners will never be tired of reading and writing about growing (and I ought to say keeping) Grapes. As Mr. Robson observes, we want experience of failure as well as success; we want practice more than theory.

My opinion, which is gathered from experience, is to cover the borders early and late. As to the material employed, it ought to be something that will entirely keep off the rain. For several years I covered with leaves from a foot to 18 inches deep, and then thatched with straw as well and as carefully as I would a corn stack; but when I uncovered them I found the borders very wet, particularly near the front, for owing to the little incline of the thatch a large portion of the rain went through the leaves.

I found in January the temperature of the border at 1 foot deep was only 6° warmer than the open ground; I also found

a few feet from the vinery that the heat of the leaves had caused a strong root action, for the roots had grown several inches and were matted into the leaves, but they had nearly all perished. I had carefully taken the time of the men collecting leaves, thatching, &c., also the value of the straw, and we found that it would cost as much in eleven years as we could cover the whole with glass, consequently the whole of three borders have been covered with that material. We find the lights very useful during the summer for various other purposes.

I know a Vine border in this neighbourhood that is only covered with fresh dung in autumn; the Grapes grow fine until they begin to ripen, then they completely fail: this has been the case for several seasons. I think it more needful to exclude wet than to create artificial heat. On my borders I put about 6 inches of nearly fresh stable dung; then (except the late house) leave it to have a thorough soaking of rain to take the food down to the roots, ready for them when they begin to grow, also to wet the border to its bottom; then I put on the glass, where it remains until I think the open ground is as warm as the covered border. I generally have to water twice before I uncover.

As to the late Vines, I put on the dung as on the earlier borders, but after September I do not let any rain fall on the border until all the Grapes are out. I then take off the glass and let the border have a thorough soaking of rain for several days, then cover up as before.

With regard to keeping late Grapes, it is of more consequence to have a dry atmosphere than dry roots. This autumn I put on the glass; not a drop of the heavy rains fell on the border, but owing to all the hot-water pipes being altered and no boiler in, with wet soil turned up where the mains are along the back part of the house, I could not keep a single bunch of either Muscat, Alicante, Lady Downe's Seedling, or West's St. Peter's. I have experienced this before, when I could not apply heat to dry the atmosphere.

It is very essential that late Grapes be ripened early. If they are to keep well they ought to be ripe by the middle of September.—D. WALKER, *Dunorlan*.

#### PEACH FORCING.—No. 6.

**WATERING.**—Trees—deciduous trees no more than evergreens—require during their resting period a soil "dry as dust," and it is altogether a misconception to attribute any good resulting therefrom, either as regards further ripening of the wood, for that ceases with the fall of the leaf, or as promoting greater rest. Instead of dryness whilst at rest being beneficial, I am certain it is in most instances and with most subjects positively injurious, for trees transpire by their bark when the atmosphere is dry, which, with the roots in a dry soil, causes a speedy exhaustion of their juices. The consequence of this is a certainty of weakness at starting, if not of after-debility, for fruit trees in autumn emit in most instances direct from the root-stem adventitious roots, thick, spongy, and white; but if the soil be dry those roots are never emitted, nor are they emitted until spring if the trees are moved after all the leaves have fallen, or the act of removal destroys them, and they are not afterwards put forth: hence the potting of fruit trees in pots is done whilst the trees are in leaf, experience having shown the disastrous consequences of performing the operations after the trees are leafless. Apart from the promotion of adventitious roots, moisture in the soil maintains the shoots and buds fresh and plump, for if the fibres or their soft unripened parts die as do the leaves, which I have maintained and still do maintain, the root-stems from their sides will absorb sufficient moisture without the presence of spongy, as is the case with trees transplanted after the fall of the leaves, and upon the presence of this moisture in the soil is dependant the retention of the bloom buds.

Instead of keeping the roots dry whilst at rest I advise that the borders, when the leaves of the Peach and Nectarine trees under glass have all fallen, be given a thorough watering, loosening or breaking the surface if it has become cracked from being hard and dry, and taking care that as the soil may be dry it will require considerably more and longer-continued watering to bring it into a thoroughly saturated condition. No fear need be entertained of rotting the roots, as the Plum outdoors must have during the winter season a rainfall of 12 to 15 or more inches, and it is noteworthy that Peach trees outdoors subjected to this heavy rainfall do not drop their buds, whilst those under glass kept dry at the roots do, which is

primarily caused by an exhaustion of moisture from the tree, though the effect may not become apparent until water is applied to start them into growth, but causing the buds to be cast in a shower, which a timely application would have prevented. Never was sounder practice recommended than that of Mr. Douglas—viz., the placing of pot Peach trees outdoors in the autumn. The trees suffer no injury, the pots being plunged; the buds do not drop, starting when returned to the house with a vigour not exhibited by those kept in the house with the pots stood on the borders and kept dry to save the roots from injury from frost. It is bad practice keeping the roots of trees dry whilst at rest, which naturally receive a rainfall very little less at that period than during that of growth.

Not only after the leaves have fallen should a thorough watering be given, but before starting again repeat it, so as to bring the soil into a thoroughly moist state; and this is of some importance, inasmuch as it is not desirable to have to water after the blossom expands, as, if the weather be dull, the watering causes too moist an atmosphere for setting, and the young fruit does not swell kindly if recourse is had to watering immediately the fruit is set, as the watering causes an excessive supply of sap which the trees have not leaves to elaborate, and the growing parts are stimulated, the production of shoots being rapid, whilst the fruit drops from not growing equally fast. If the soil be in a thoroughly moist state when forcing is commencing no water will be required until the fruit has attained the size of horse beans. The trees by that time will have some foliage, and their drain upon the soil for nutriment by the roots considerable. From this stage and onward the supply of moisture to the roots must be liberal, and it must be given at a temperature equal to that of the mean of the atmosphere, for though watering with water less in temperature may not cause any present apparent evil, it may cause the fruit to swell irregularly, if not to cause its subsequent falling.

Wherever forcing is carried on there should either be in the house a cistern of sufficient capacity to water not less than a fourth of the extent of the border, never using it until the water has been in the house twenty-four hours; or if the house could not conveniently have within it a cistern to water the whole extent of the border at once, which is certainly more desirable than watering a part of the border daily, it may be sound economy, as it certainly is sound practice, to employ water not less in temperature than that of the border at the time of application, which may be easily ascertained by a ground thermometer, and to effect this hot water may be drawn from a cistern for heating to a proper temperature; but a preferable plan to either is to have a large cistern conveniently situated in a shed, and of such size as to water a considerable part, if not the whole, of the border of a house at once. The supply should be regulated by a tap. To heat the water in the cistern we have only to connect a lead pipe (inch bore) to the main flow of the heating apparatus, entering the bottom of the cistern at one end, and a corresponding pipe at the other end, and connected with the return pipe of the heating apparatus, and upon both these pipes should be stop-cocks, closed when the water is being drawn off or not required, and open to heat the water in the cistern. The level of the water in the cistern should be that of the water in the supply cistern of the heating apparatus. A pipe from the cistern leading through the wall into the houses will, of course, be needed, and being fitted with a tap to receive a hose pipe, the water from the cistern may be used anywhere with a hose pipe whose level is below that of the bottom of the cistern. With means for warming the water employed there is nothing to fear, but without such means much to dread. We find in all works on gardening water is to be given at the temperature the plants are growing in; but not many places have means for giving this essential element at its proper temperature, or only in very inadequate quantity, for the dribbles from watering pots are for fruit borders useless, they not requiring gentle waterings, for that is given by syringing, but a thorough wetting of the soil to its fullest extent. Any excess will, if the drainage be good, pass away.

Now, after the fruit has attained the size of horse beans a good watering should be given, and repeated every fortnight until the leaves are full-sized, after which water every ten days, continuing this until after the stoning, and then water every week until the fruit is ripe, and after about the fourth of the fruit is gathered let the watering be at fortnightly intervals, giving such waterings, say every three weeks, after a month from the fruit being all gathered as will keep the soil

in a moist state, which is essential to the maturation of the buds and the maintenance of the foliage in a healthy state. Excess of moisture after the fruit is gathered only tends to growth, whilst dryness causes the leaves to fall prematurely whilst the buds are imperfectly developed and the wood not fully ripened. Considerably less moisture is, of course, required after the fruit is gathered, but it is nevertheless an error to dry Peaches into ripening of the wood as speedily as possible after the fruit is ripe; then, as at other times, they require a moist soil. As to the amount of water to be applied, that is to some extent influenced by the condition of the trees and their occupation of the border by roots. Young trees will require greater watering near the stem and less at a distance than older trees, gross-growing trees requiring careful watering, for to water such very freely is only to make them more gross, and weakly trees will need less but more stimulating nutriment than those trees having that happy medium between grossness and weakness.

The quantity to be applied at a time is expressed in terms indefinite, as "moderate, copious, liberal, free, and thorough soaking." I have often wondered how amateurs interpret these terms—I do not intend to include in that category those amateurs as well skilled in watering as most professionals, but the novices, to whom I may just give a hint. A plant in a pot with the soil half an inch below the rim will receive every time it is watered the equivalent of half an inch of rainfall, or about as much as usually is given by the clouds to the earth in a week; an inch below the rim will represent an inch of rainfall, and 2 inches below the rim 2 inches of rainfall. Now it follows that half an inch of rainfall will only penetrate or moisten soil to its retentive power to half the depth of that having an inch, and the inch to only half the depth of 2 inches, and if we put it this way we are not far wrong. Half an inch of water space will moisten soil 4 inches deep, it not being other than so dry as to maintain a plant fresh, but if flagging from dryness two or more such waterings may be required to thoroughly moisten the soil. An inch will penetrate 8 inches deep, and 2 inches 16 inches or more deep. No one knowing anything of plant life would water a plant if the soil was already wet, and it is not presumed that anyone will ignore such a condition in the application of water to fruit borders. It may be that water is advised to be given every fortnight, but it is not considered that anyone will not exercise his own judgment as to whether the soil is not already moist and does not require it, deferring the watering in such case until such time as it is needed, or giving the watering sooner if required. A light open soil requires twice the quantity of water needed by a close heavy one. An inch of rainfall is equal to half a gallon of water per square foot, or four gallons and a half per square yard. Granted we have a house to water 60 feet by 12 feet, we shall require 360 gallons of water—the equivalent of 1 inch rainfall, and for this purpose we shall need a tank or cistern containing 360 gallons of water, or of these dimensions 6 feet long, 3 feet wide, and  $3\frac{1}{2}$  feet deep, internal measurement, containing 68 cubic feet, which at six gallons per cubic foot would give 378 gallons; but as there is always some waste in artificial watering, and as some parts of the border will require more than the quoted inch to bring it into a moist state, or equal to other parts, we should not have a cistern of less size than one-half greater in water-holding capacity than the quantity required to give the equivalent of an inch of rainfall, as we must bear in mind that natural waterings are gradual, whilst artificial are "downpours," much of it passing away by parts of the border more porous than others without passing gradually down equally as in the fall of rain.—G. ABBEY.

#### ISLE OF JERSEY.

THE following is an extract from a letter dated the 22nd inst., from a resident in the island. Even the name of the locality—Val Plaisant—is genial. "All the time of that severe frosty weather in London we had no frost, and but a very slight fall of snow, which melted as soon as it fell. We have some Carnations in full bloom in our garden, and the Geraniums are still quite flourishing."

We have often expressed our surprise that invalids needing a mild climate do not steam over to Jersey, which is about one hundred miles from our southern coast, and is reached in a few hours.

Evidence of the greater mildness of the climate, even than that of our south-western counties, is proved by the fact that

plants in the island require no protection which have to be sheltered in Devon and Cornwall. In no place does the Apple tree flourish better or bear more unfailingly; its orchards are so numerous as to be a feature of the island, and its Chautmontel Pears, both for size, excellence, and abundance, are justly celebrated. One weighing  $30\frac{1}{2}$  ozs., was exhibited some years ago. Nowhere is the Parsnip grown finer or to greater extent; its culture is a peculiarity of the island, and is called "*la grande charrie*." The soil has to be stirred very deep, and a plough requiring many oxen or horses is employed, and as these cannot be supplied from one farm neighbours unite their teams; and this ploughing is a holiday, for not only are cakes and cider provided during the day to the owners of the cattle, but the day concludes with a supper. The Guernsey Lily (*Nerine sarniensis*) is common, but does not flourish so markedly as in Guernsey. Some of our readers may not know the narrative of its introduction. Dr. Morison says a ship coming from Japan with bulbs of this flower on board was wrecked on some of Guernsey's many rocks; the bulbs were thrown by the waves on to the sandy shore, and were soon buried there. They produced flowers in due time; and the second son of the Governor, Lord Hatton, being fond of flower-gardening, cultivated them, and sent bulbs to many persons in England. This was in the reign of Charles II.

#### OUR BORDER FLOWERS—HELENIUMS.

SOMETIMES we meet with some of our neglected border flowers quite unexpectedly, and on the question being asked, "What have you here?" a common reply is, "Oh, it is an old plant we take no notice of. We don't care about such plants here;" but these plants ought to be cared for, for nearly all our border flowers possess attractions rendering them worthy of cultivation. Seldom do we meet with any of this family of plants in our fashionable gardens; a few of them may be seen in choice private collections, and can only be looked on as rarities. They are a race of plants that will thrive in any ordinary garden soil, but are all the better for being liberally treated. Loam and well-decomposed vegetable matter, and coarse sand mixed with the soil where they are intended to grow (and the ground should be broken up to the depth of 18 or 20 inches), will afford them the sustenance they need. They should have thorough drainage, and be supplied with water when required. Some of them, growing from 2 to 3 feet high, require staking to keep them from being broken by the wind. They may be increased by division in spring or autumn, and they flower towards the latter end of summer and in autumn.

*Helenium pumilum* is the dwarfest of the tribe, and is a good border plant, having bright yellow flowers, which make a fine display when well established. *H. Hooperii* is decidedly the best of the family. This plant is so seldom seen that it cannot be much known to cultivators of herbaceous plants, or I am inclined to think it would be more frequently met with. When planted in open spaces in the shrubbery in good soil it is extremely effective. To see it in all its beauty the weakest growth should be thinned out, and the plants be supplied with liquid manure water occasionally. It is excellent for exhibition purposes, and continues long in bloom. *H. autumnale* is a fine autumn-blooming plant of taller growth than the preceding, and is well adapted for border or shrubbery decoration, producing large flower heads, which continue until they are destroyed by frost.—VERITAS.

#### ROSE OF JERICOHO.

THIS is *Anastatica hieracifolia* of botanists, which the monks of old invested with such miraculous powers, and which the people regarded with such superstitious veneration. The plant is small, bushy, and not above 6 inches high; after it has flowered the leaves fall off, the branches and branchlets dry and shrivel up, incurving towards the centre, and, in fact, forming the plant into a sort of ball. They are easily uprooted from the sand by the winds, and are carried, blown and tossed, across the desert into the sea. When they come in contact with the water the plant unfolds itself, the branches are expanded, the seed-vessels open and relieve the seeds, which are conveyed by the tide and deposited again on the shore. They are carried hence by the winds away into the desert again, and there they take root, producing plants which in their turn perform the same strange part in the economy of creation. It was to this property of expanding

when placed in contact with moisture which induced the marvellous and superstitious importance of the plant, and it was believed that this appearance always took place on the anniversary of the birth of our blessed Saviour. The plant may be kept for years if taken up before it is withered and then preserved in a dry room; at any time when the root is put in a glass of water, or the whole plant immersed, it will expand, and, in the course of a few hours the buds of flowers will swell and appear as if newly taken from the ground.

Possessed of extraordinary vitality is the plant now figured. It may be called a toy plant, and few other toys will give more salutary teachings. It is also appropriate to the period. The old year is closing and the new year opening; the plant is old and collapsed, apparently dying; but nourish it, and in the few hours still remaining of the old year the plant and new year will awake together.

Further, both the plant and year are what we make them;

level, but which in reality is not so; nevertheless, the whole work is of such a nature that without some judgment at the commencement as well as in the process of the work, some great error may be run into which may render the ultimate completion of the work both difficult and needlessly costly. To obviate this let us take a survey of the whole before a spade is put in. By the exercise of some of the rules of geometry, aided by what is still more serviceable—the judgment of the eye, a rough idea may be formed of what number of slopes and their elevation, as well as the number and widths of the terraces or landings, the ground may be conveniently formed into. The hard-and-fast lines of the architect in all cases that I have witnessed means a larger outlay than the prudent gardener would recommend; as when material has to be brought, or it may be taken away, in order that a precise width of terrace or height of panel to an inch may be complied with; whereas a little discretionary power given to the

Fig. 118.—BORN OF JERICHU

by our efforts each may be made joyous. Without kindred nourishment the plant sleeps, but kindness bestowed it returns cheerily. So with the year; and as the assistance received by the plant makes it forget past neglect, let us in the new year forget and forgive any neglects which we may have experienced. Obstacles and impediments have beset the paths of all. Employers and employed have alike been tempted to utter hard words and, mayhap, commit harder acts. Let these be as if they had never been, and, like the newly nurtured plant, the new year will flourish.—W.

#### GROUNDWORK—SLOPES AND TERRACES.

ALLUSION has been made to inclinations on lawns and terraces appearing to the eye as being level—a subject well worth the notice of those contemplating groundworks of that kind. The usual accompaniment of a terrace—viz., "the slope," is sometimes dispensed with when a wall is adopted, but it is common where there is a number of descents made to have the top one only as a wall with balustrade or parapet, and the others constituting a series of slopes, which may either be of turf or shrubs as desired. As such works usually come under the management of the resident gardener, a few hints may be of service. Let us take a common case as an example. A residence occupies a rather elevated position, and the ground descends from the base of the building in the direction in which it is proposed to form dressed grounds. In such a case it is not unusual to cut the slope into a series of terraces, and at the bottom to form a panel, which to the eye appears to be

operator will usually save a large outlay, and the appearance be really the same.

Taking into consideration the ultimate effect that is looked for in a place carried out in slopes and levels, especially when viewed from the top, we may say that where the builder's work does not dictate the forms the gardener has to work to, a certain amount of conformity to the existing grounds may be made with great advantage; and even mechanical works, as steps and landings, ought to be made to act in like manner. The advisability of this is not for mere appearance only, but for the more imperative object of utility. Many years ago we remodelled some slopes that form the garden front of the mansion here (Linton Park), and added a flight of steps, of about 15 feet wide and forty-seven in number, in a series of flights and landings, and each step inclined outwards about one-eighth of an inch, while the landings had likewise an inclination of about 1 in 30 or thereabouts, the groundwork partaking of the same character, while the slopes which corresponded with the easy and comfortable flight of steps were formed on the gradient of about  $2\frac{1}{2}$  base to 1 in perpendicular; or about  $20^\circ$ —a slope for grass quite steep enough in a district like this where the summer drought tells so seriously on grass slopes. A moister soil and north aspect may allow a steeper incline perhaps, but we would not advise a less incline than what mechanics call 2 to 1 in ordinary cases, as it is not easy to walk up a steeper one. Many other reasons might be put forth for not having a steeper incline than that, not the least being the frequency the turf gets broken and destroyed when it is too steep; and unless some important

reason renders it necessary to be so, it had better have the easy and agreeable form which the gradient above gives it than it would have if it were more upright. I may here add that embankments for roads or other purposes ought to be even more than that. A base of 3 to 1 perpendicular is not unusual where the material is of a very loose kind, but a cutting may be steeper; and our railways afford examples of all gradients from 60° or more down to 15°, and some of the embankments also present a diversity of angles, all, doubtless, guided by the character of the material of which it is composed and of other matters bearing on the case.

We now come to what are called levels, but which in reality had better be inclines also; not, of course, to appear to be so, but by appearing to conform to the surrounding objects they look level. A panel we have here at the base of the flight of steps alluded to has a length and width of about 160 feet, and there being a farther fall in the ground beyond the distance alluded to a decline in that distance was necessary. Partly to give the effect alluded to, as well as to obviate the necessity of a needless amount of wheelbarrow-work, the descent of the 160 feet was quite 6 feet, and less would certainly not have looked so well. As viewed from the top it appears level, which it would not have done if really so, as in that case it would have looked as if it leaned inwards. This deception of the eye ought to be studied by those having such works in view; and a very good example may be met with in winter when a pond by the side of some hill is frozen over, and perhaps covered with snow. Perfectly level as we all know such an object must be, its appearance when looked at from above is anything but pleasing, and certainly the reverse of level, looking as if it pitched in towards the hill. It is to obviate this that I recommend the incline above spoken of, or some near approach to it.

I may here add that the incline recommended for the steps and landing enables the water to run off, which it would not do if each portion were level and the rain backed perhaps by a wind blowing in the direction to keep it there. This matter is well worth consideration, and each step ought to "weather," as masons have it, not less than the eighth of an inch, and the landings accordingly.

I may, in conclusion, say that I believe a croquet lawn may be allowed the same descent as that alluded to above without any serious detriment to the game. Perhaps, however, I may be in error here, but having had something to do with more than one which presented an inclination of something like 1 in 30, and not having heard anything against its working well, I take it for granted that its unevenness was not perceptible to the players. But on this subject I confess speaking without any authority, and must leave this to be dealt with by those better acquainted in such matters.

I have not said anything on the propriety of keeping the best soil to the top, as I conclude this will be sufficiently well understood if the works be in the hands of gardeners. On another occasion I may, nevertheless, add a little more on this head, on which not a little of the ultimate effect depends if the ground operated upon has to form a series of flower beds or to be otherwise planted.—J. ROSSON.

### NEW ZEALAND GARDENING.

THE accompanying letter addressed to the Secretary and officers of the Maidstone Gardeners' Mutual Instruction Society, from one of its former members, will no doubt be interesting to some of your readers, as it relates to matters both general and horticultural. The writer, a steady, industrious, hard-working man with a young family, had previously to leaving England been acting as general outdoor servant to a clergyman near here, whose garden he had taken much pride in. Wishing to improve his position he emigrated to New Zealand, with what result I leave his own letter to tell. I may, however, add that he was a frequent attendee of the meetings; and although too modest to take much share in the discussion he was much respected by the members, and his letter proves that he has not forgotten his old friends. His letter being read to the meeting was duly appreciated, and a reply will be made in due time.—J. ROSSON.

"Gentlemen,—I am happy to inform you that I arrived here on February 12th, 1875, and am sorry to say I lost a little girl on the voyage, which is the only trouble noticeable I have had since I left home. I was ten days before I could obtain a start, and then I started jobbing gardener, and have not wanted a day's work since. I earn 9s. and 10s. a-day, according to the

work and party I work for. I am just finishing laying out the cemetery. It has been a good job. I have planted upwards of a thousand trees—coniferous and forest trees and shrubs, besides other work. The subsoil is very hard and has to be removed, filling up with other soil, or the trees cannot grow on these high and dry hills.

"Gardening here is very different to that at home (England). Very little bedding-out is done here, the gardeners' object being to raise as good a collection of Conifers and forest trees and shrubs as possible; and the one that can save most is the man they look to, as a great many trees are planted only to die. We have a good collection of Pinuses, Cupressuses, Araucarias, and shrubs. Pines are planted by the million, especially *P. insignis*, *P. Pinaster* (maritima), and *P. austriaca*. *P. insignis* is the fastest grower, and the *Pinaster* grows better than any other on dry hills; but *P. monticola*, *P. densiflora*, *sylvestris*, *Torreana*, *tuberculata*, and many others soon make fine trees if planted well. *Cupressus macrocarpa*, *C. horizontalis*, *C. Goveniana*, *C. Lambertiana*, and *C. Lawsoniana* are very plentiful.

"The great object is to provide a good shelter to a gentleman's place as quickly as possible, and for that purpose the Blue Gum (*Eucalyptus globulus*) has been employed, as that is the quickest-growing tree we have. Seed sown will make a good shelter in about three years, but they have stopped using it now so much, as it robs everything that is near it.

"Geraniums grow on year after year as large as Black Currant trees, and we have them covering an 8-feet wall and hanging over the top like Ivy, and covered with flowers nine months out of the year. Our spring is just commencing now (Sept. 26th). We are just pushing on the last tree-planting; fruit trees are past removing now. We have a pretty plant that was raised in the colonies, *Photinia serrulata variegata*: the leaf is tricolor. We keep obtaining the new Roses; some of them do remarkably well on their own roots, especially Cloth of Gold.

"And now I will tell you a little about Comorn. It is a new town close by the sea, and is in a very prosperous condition at present, but things are very dear. We have to give 7s. 6d. for a spade and 5s. 6d. for a three-shilling Saynor's pruning knife; 2s. 6d. for a pair of gloves worth about 1s. at home. Any gardener coming out should bring plenty of tools. Furniture and all kinds of hardware are dear; coals, £3 10s. per ton; butter, 2s. 6d. per lb.; bacon, 1s. 8d.; bread, 1s. 4d.; flour, a 50-lb. bag for 6s. 6d., and a two-roomed house is rented at 10s. per week. I mention these few things because they do not do it at home; it is only the cheap things that they put in the newspapers. But Comorn is about the dearest town in the colonies, as the goods are brought by water and have to be landed in surf boats; but we had a railway started yesterday, and another going on.—JOSEPH BAKER."

### RIVERS' PEACHES IN TEXAS.

HEN at the Rosedale Nurseries we find all the following kinds of Rivers' Peaches to be very heavy croppers, and feel confident that with timely care and thinning they could be brought to great perfection. With the exception of Early Beatrice they are too soft for shipping. These notes, however, merely apply to what they have done with ourselves in Central Texas, and cannot be taken as a criterion of what they may do elsewhere, fruits being so variable even in neighbouring communities, let alone States. I know Rivers senior and junior, and Sawbridgeworth too, and a better recommendation to a new fruit than "raised by Rivers" I would not wish for; but at the same time, what may be very excellent in the north or in Europe may be ill fitted for Texas, and *vice versa*. As a rule, however, nearly all kinds of Peaches do well here; indeed, Texas is one of the best Peach-growing States in the Union.

Early Beatrice is a very beautiful little fruit, suffused all over with red, and when fully ripe the flesh is very melting and juicy. It is an enormous bearer; indeed it crops much too heavily for the good of the tree or the quality of the fruit, but I believe if early thinning were resorted to (and that we have no time here to do, where so much other work demands our presence) it would be greatly improved in size and quality. The fruit has the rare quality of hanging on the trees for ten days after it is fully coloured and marketable, but that is no advantage, as it then treads on Hale's, with us the largest and most saleable Peach of the two. The fruits are firm-fleshed and stand carriage well, and we have never known them to rot on the trees or be attacked with worms. In 1873 it ripened here on May 15th, in 1874 on May 18th, and this year, 1875, on May 25th.

Early Louise is medium-sized, yellowish, with a red cheek; it is melting, very juicy, and as sweet as honey. It does not crop nearly so heavily as Early Beatrice, and is too soft for shipping, but as a family Peach it is delicious. It ripens during the last week in May.

Early Rivers is one of the most beautiful of early Peaches, large, and of a pale straw colour with a warm rosy cheek—just such a fruit as Eve could not resist. Its flesh is melting, juicy, and delicious, and in size and quality it has few if any seasonable superiors as a family Peach, but it is too soft to ship. It ripens at the same time as Early Louise—end of May.

Early Victoria before it ripens is one of the dirtiest-looking little Peaches I know of, but from ten days before up till the time of its maturity it undergoes quite a change, and gets moderately pretty—a rusty white with red cheek. Its quality is honey. Its size is medium, time of ripening early June, and although a fine family fruit it is too soft for shipping.

Stanwick Early York is a pretty little Peach, white, a good deal covered with red. It is a very heavy cropper, but much too small to compete with such sorts as Large Early York, Mountain Rose, and other fine kinds of the same season. It is not nearly so big as Troth's, nor yet so fine-eating as the true Early York, and it is the most wormy little Peach I know of. It drops badly in dry weather.

Rivers' Early York is not much unlike Stanwick Early York in size, colour, or quality, but it is not nearly so bad with worms, and if anything it is a trifle earlier, this sort being quite gone whilst a good third of the preceding still hang on the trees. Both ripen about the third week in June.

Prince of Wales is a beautiful creamy-coloured fruit highly coloured with red, from medium to large in size, of excellent quality, and ripens about the end of July and 1st of August. It is a great cropper, and with a little care in thinning it would be a first-class family Peach. Owing to last summer's extreme drought more than half the crop fell; but it was not alone in that, as many standard kinds, as Wilson's Early, Druid Hill, Stump the World, and Ward's Late were equally faulty.—W. FALCONER, Brenham, Texas.—(*American Gardener's Monthly*.)

### NEW BOOKS.

*Elementary Lessons on Botanical Geography.* By J. G. BAKER, F.L.S. London: Lovell Reeve & Co.

BOTANICAL GEOGRAPHY is a subject which is rarely presented to gardeners in a popular form. The treatises which have hitherto been written on the subject are expensive and elaborate, or have been incorporated with botanical works which are at once philosophical and expensive. In the little volume which has recently been published by Mr. J. G. Baker we have the subject presented to us in clear and simple language, which makes it easily intelligible to those who would be bewildered if it were treated in conjunction with physics and biology. We give as our illustration an extract from the chapter "On the Manner in which Heat Influences the Distribution of Plants:"—

"The influence of temperature upon the distribution of any plant depends largely upon its season of vegetative activity. Annuals, which run their course from the seed stage to leafing and flowering, and back to the seed stage, in a period varying in length from two to six months, can only be affected by the temperature of that portion of the year during which they are growing. Biennials have to last through the winter, and often concentrate their energies for a large proportion of their existence in storing up materials in their rootstocks, and spring up into flower and seed in a short time when warm weather comes, at the expense of tissue previously elaborated. Trees and shrubs have usually a well-marked time of flowering and fruiting once a year, and it is the same with a great many perennial and annual herbs, but the season with different species is very different. *Eranthis hyemalis*, and the Snowdrop and spring Crocuses, push out their flowers and leaves as soon as the snow melts. Hawthorn and Blackthorn, and our common fruit trees, push out their flowers in April and May, before the leaves are developed or perfected. The flowering of Ragwort and St. John's Wort takes place long after the leaves appear, and marks that the summer equinox is past, and the days are beginning to shorten. *Colchicum autumnale* produces its flowers regularly in August, but its leaves not until the following spring; while *Asters* and *Chrysanthemums* flower regularly at Michaelmas; and Holly and Ivy, and Aucuba, and Cherry-Laurel, are in full leaf all winter; and *Lamium album*, *Poa annua* and *Capsella bursa-pastoris*, may be seen during any month of the twelve in simultaneous leaf and flower. So that the time of the year at which different plants are at all sensitive, and especially sensitive to temperature, varies extremely.

"It is evident that, in the first place, plants need very different degrees of temperature to start them into life. The seeds of many of the Microtherms, and even of plants of our middle latitudes, will germinate at a temperature of little over 32°. Of cool-temperate species, for which the experiment has been carefully tried, *Sinapis alba* has been found to germinate at 32°;

*Lepidium sativum* and *Linum usitatissimum* at 35° to 36°; *Nigella sativa*, *Iberis amara*, *Trifolium repens*, and *Collomia coccinea* at 41° to 42°; and Wheat, Barleys, and Oats at 44° to 45°. With heat added over and above these degrees the time from the sowing of the seed to its germination is found to be materially shortened. *Sinapis alba*, which took seventeen days to germinate at 32°, was found by M. Alphonse De Candolle to take sixteen days at 35° to 36°, nine days at 37° to 38°, four days at 42°, three and a half days at 48°, one and three-quarter days at 51° to 52°. Passing to Mesotherm types, the temperature needed for germination becomes gradually higher. For Maize it is stated to be 48°, and for the Macrotherms at least 50° to 60°, but it may take place at a much higher temperature. *Sesamum orientale* has been found to germinate in nine days at 51° to 52°, in three days at 62° to 68°, in thirty to thirty-six hours at 68° to 69°, in twenty-one to twenty-two hours at 75° to 76°, in twenty-five hours at 82°, and some even in ten and a half hours at a heat of 104° to 105°.

"The start once made, it is evident that plants need a certain amount of heat to enable them to flower and fruit, but that, with some species at any rate, it is immaterial, within surprisingly wide limits, whether the heat come gradually or rapidly; and that if the latter, the times of flowering and seeding are accelerated. Nothing shows us better how flexible in this respect a plant may be than the familiar facts about the sowing and harvesting of the common cereal grains. In the north of India, Wheat is a common winter crop, to be followed in summer by Maize or Indigo, and is sown, and the harvest gathered, within three months. In Palestine the Barley ripens at the end of March, and the Wheat by the end of April, November being the month of ploughing and sowing. In Malta and Sicily they sow at the end of November, and harvest through May. In the countries round the north side of the Mediterranean basin they sow early in November, and harvest in June. In Central Europe they sow in October, and harvest in July. On the Yorkshire wolds and in the Alpine valleys of Switzerland they have to sow in September, and cannot harvest till the following August; so that the time that elapses between sowing and ripening may be said to vary between the different parts of the tract in which the common cereal grains are cultivated for the use of man, on a grand scale, from 90 to 320 days. If too much heat be applied the embryo refuses to germinate; or if it has germinated already, the leaves, or flowers, or fruit, according to the stage which the plant has reached when the hurtful heat is applied to it, are not developed.

"Then, again, it is equally evident that a gradual or sudden access of cold below a certain point—a point which varies with different species—coming when the plant is in a state of vegetative activity, injures or kills it. It may be simply a cold north-east wind in spring, blighting the blossoms of the Apricots, and Apples, and Pears, and whilst destroying the seed for the year, doing no permanent harm to the tree; or it may be a mild frost at the beginning of winter, cutting off entirely our garden Dahlias, Pelargoniums, and Mesembryanthemums; or a hard frost in the middle of winter, killing the Eucalypti, Araucarias, Hollies, and Aucubas.

"It follows from these familiar facts that some plants are checked from spreading from warmer latitudes towards the poles by the want of plenty of heat in summer to carry them from the seed stage, round the circle of life, to the seed stage again; and that others, for which the heat of summer is sufficient, are cut off by sudden fits of cold that catch them at a time of vegetative activity. It is of no use, it seems to me, attempting to treat this last matter in close detail as a question of figures and thermometric degrees, because the different habits of growth of plants, and the different degrees of the wateriness of their sap, dependant upon the hygrometric conditions of the surrounding atmosphere and soil, influence it greatly, and their vegetative action passes through so many intermediate stages between the fulness of life in spring and their nearest approach to a dormant condition. But we may safely distinguish broadly between the two great classes of plants which I have indicated, and which I will call the *Heat-lovers* (*Philotherms*) and *Cold-fearers* (*Frigofuges*). Annuals are usually heat-lovers; trees and bushes, especially evergreens, are usually cold-fearers; and it follows, from what has been explained already about the characters of the two kinds of climate, that the cold-fearers can work up further from the equator in insular, and the heat-lovers in continental, climates."

This is a work which we can commend to the study of all gardeners, whether amateur or professional, as being a clear exposition of laws which materially affect the cultivation of plants.

*Handy Book of Ornamental Conifers and of Rhododendrons and other American Flowering Shrubs.* By HUGH FRASER. London: Blackwood & Sons.

THE work before us is a useful one to lovers of Conifers and of what are called "American plants"—two families of

the vegetable kingdom which contribute perhaps more of ornament to our shrubberies and gardens than any other. Mr. Fraser's great experience as a nurseryman in one of the largest, if not the largest, nurseries of Scotland, enables him to write and speak with authority on such a subject, and in this handy book he certainly communicates without any reserve an amount of information which is useful and instructive. As a manual to planters it will be of great service, and as a book of reference to gardeners and nurserymen it ought to find a place in every establishment. All the information respecting the subjects upon which the book professes to treat is exhaustive. We could only wish that Mr. Fraser had given us the characteristic distinction of the different species of the Conifers, which would have made the work complete. We know of no handy book which gives us this information—to distinguish, for instance, the essential characters of the different species of *Cupressus*, which are in some cases very puzzling. A few synonyms would also be a great help if added to the different specific names. But even without these Mr. Fraser has given us a very useful book.

### PLANT PROTECTOR.

As usual at this time of the year we have numerous applications for advice how to protect plants—applications which

prizes at these exhibitions is £2500, the prize money on all occasions to be paid on the first day of the Show. To further add to the attractions Mr. W. W. Robertson, the Manager, has purchased the Cruikshank Art Collection, which will be arranged under the personal superintendence of Mr. George Cruikshank, and will be exhibited in the Art Galleries of the Society at the close of the first annual Fine Art Exhibition. Over two thousand paintings have already been sent in, and the Exhibition promises to be one of unusual excellence and interest.

—We recently noticed the increasing employment of SEA-WEED as a manure, and one nurseryman told us that "it made the things healthy;" and he wrapped seaweed round the broken part of an Apple-tree branch before he tied splints on each side of the fracture. It has been found similarly useful to mankind. Pliny tells of a man who fell from a tree and broke many of his bones. He was merely kept enveloped in seaweed, and eventually recovered. The people of Provence apply seaweed to contusions. Following these hints the great reviver of sea-bathing in Europe, Russell, satisfied himself that "Nature herself supplies us with the best medicine for dissolving tumours in the *Quercus marina* or Sea Wreck at one season of the year, for in July this plant bears certain vesicles or pods that contain a slippery and soapy juice. These vesicles are to be squeezed in the hands and the tumour rubbed with them till it imbibes this soapy liquor; and, lastly,

Fig. 119.

should have been made before the winter arrived. To those who are willing to obtain a protector ready made we recommend attention to the following. It is manufactured by Messrs. Messenger & Co., and they thus speak of it:—

"The lights can be opened to any extent for ventilation, or they can be run completely under the light on the opposite side, and that it is held open perfectly secure by iron pins, leaving the gardener's hands free for working, as shown on the illustration. It is made either with the sides of three-quarter-inch slate or 1-inch wood, or it is set on brickwork. It is adapted for protecting plants, or for forcing as a ground vinery, or for growing early vegetables and salads. Any length can be added at future times."

A gardener who has used protectors of this nature speaks of them as being invaluable aids in any garden large or small. He has used them for bedding plants, French Beans, Violets, &c., and as shelters for many tender crops in winter and spring. In the summer and autumn they gave an abundant supply of Cucumbers, and for growing collections of plants, as *Palargoniums*, *Primulas*, *Cinerarias*, *Poinsettias*, &c., he found them of the greatest value.

### NOTES AND GLEANINGS.

We are glad to be able to announce that a farther sum of £100 consols has been purchased in the names of the trustees for the Gardeners' Royal Benevolent Institution, and that the amount now standing in their names is £10,700.

—As advertised in our columns, the Royal Aquarium Summer and Winter Gardens Society propose holding a series of GRAND FLOWER AND FRUIT SHOWS on the following dates:—April 12th and 13th, Forced Rhododendrons, Azaleas, &c.; May 10th and 11th, Roses in pots, Azaleas, Palms, and Table Decorative Plants; May 30th and 31st, Grand Exhibition of Plants and Fruit; July 5th and 6th, Great Rose Show and Dinner-table Decorations; and October 4th and 5th, Great Fruit and Chrysanthemum Show. The amount offered in

it must be washed with sea water, and dried perfectly clean. This disperses all hardinesses." This is a curious anticipation of the more recent employment of iodine. Acting on this principle, Foubert has found poultices and such applications of *Fucus vesiculosus* useful in scrofulous sores; and baths have of late years been prepared containing more or less of the mucus or slime of seaweed, and are to be had at both French and English bathing establishments; for instance, at Margate and at Ramsgate, where they are known under the name of ozone baths.

—We commend to our readers "THE AGRICULTURAL HOLDINGS ACT, with Notes and Necessary Forms for the use of Landlords and Tenants. By H. Winch, Barrister-at-law." It is only a shilling pamphlet, and might save many pounds to those who are proprietors or occupiers of land. We will make one extract.

#### "CLAUSES OF THE ACT.

"Consent of Landlord for first class.—10. The tenant shall not be entitled to compensation in respect of an improvement of the first class, unless he has executed it with the previous consent in writing of the landlord.

"Tenant's title to compensation.—5. Where after the commencement of this Act, a tenant executes on his holding an improvement comprised in the following:—

#### "FIRST CLASS.

Drainage of land,  
Erection or enlargement of buildings,  
Laying down of permanent pasture,  
Making and planting of Osier beds,  
Making of water meadows or works of irrigation,  
Making of gardens,  
Making or improving of roads or bridges,

Making or improving of watercourses, ponds, wells, or reservoirs, or of works for supply of water for agricultural or domestic purposes,  
Making of fences,  
Planting of Hops,  
Planting of orchards,  
Reclaiming of waste land,  
Warping of land,

he shall be entitled, subject to the provisions of this Act, to obtain on the determination of the tenancy compensation in respect of the improvement."

### OLD TREES.

WHAT various thoughts are called forth in contemplating old trees! What storms they have outlived, what events they

have witnessed, what shelter they have afforded, what benefits they have conferred! Some are rich in historical associations, others do duty as territorial landmarks; some are memorials of stirring events, others are monuments of some famed ancestor. Let us, then, cherish them as old friends, and render to them that honour which is their due.

Old trees have been honoured in all ages, but the gnarled Oaks, the scraggy Thorns, and the ancestral fruit trees are now more cherished than they were. They are banded and propped, supported and sustained. The good they have done is appreciated, and their usefulness even now in suggesting wholesome thoughts and healthy contemplations is recognised.

It is pleasant to see these old trees—old friends—regarded, as old friends should be, with respect. There is something in an old friend that one clings to with a confidence which we feel will not be misplaced. We like to nurture the young, and we admire the vigour of perfected manhood, or treehood; but in both tree and man we learn to lean on the stability of those which have proved their stableness. I am not yet old, but old enough to have experienced the flatterings of new friends who have failed me, and new trees from which I had hoped for more than I have obtained. I have destroyed the old for the sake of the new and have regretted it. I have changed and "changed back again," and found old friends which had "changed not;" but the old trees I have destroyed I can never restore.

But I have new friends also and new trees, generous and genuine friends, who would rather sacrifice my friendship than deprive me of that which I had enjoyed prior to theirs. That is noble friendship, and I prize it as I do my new trees which flourish by the side of their foster parents. I have other "friends," who have forced their friendship on me and sought to alienate me from the old, and thus have shown the cloven foot of selfishness, and have won—my pity; as I have other trees which have been fair to look upon, which have been full of promise—trees which have put forth a great show of bloom and vigour, but on testing their fruit—proving them—I have found them "not true to name." Thus by experience and disappointment I have been taught a lesson which others may with advantage learn also, and that is not to presumptuously abandon old friends or lightly sacrifice old trees.

I am not a kid-gloved sentimentalist, but am one of "the craft," plain and practical—one who can work hard and speak plain; of which I may give as an instance that I have wheeled muck until my hands became as hard as the barrow handles, pruned until my fingers were frozen into chilblains, and uprooted trees until my shirt was wet on my back.

Having presented my credentials I will now be practical and state my reasons for saying a word on behalf of old trees: my other old friends can take care of themselves. When I was a very young gardener I made a mistake. Many young gardeners do; they think they are making improvements, but in reality they ought to be written "mistakes." They have either planted the wrong sorts of trees or planted them in the wrong places, or, what is quite as likely, have (or would if power had been given) taken away trees which ought not to have been removed.

It should never be forgotten that in the removal of trees it is possible to undo the work of a hundred years in as many minutes. Much consideration should therefore be given before the work of uprooting commences. The destruction should not be decided in a day—hardly in a season, and that season winter; but the trees and their surroundings should especially be examined in the summer months, and the verdict condemning them be given when the trees are in their fullest beauty. By that practice errors in removal are greatly reduced.

It is dangerous to decide quickly on destroying trees at a season when the trees are divested of their beauty. The casting of their foliage, and the consequent untidiness following, must have no weight and voice in the decision; yet it is to be feared that it is often the most powerful argument—the casting vote—in the question of their removal.

It is more than twenty years since I was first installed (perhaps prematurely) in the position of head gardener. I had wearily longed for that time—the prospective "grassy Lumon"—of impatient journeymen, who seldom find it, however, to be the bed of Roses of their anticipations. I was full of energy, and possessed, at least in my own estimation, taste and competency. I must make a mark, and was ever ringing the changes on "alterations and improvements." It was autumn, and the seasonable *deshabille* of falling leaves interfered with my sense of trimness and propriety. I envied those

who had as garden ornaments none but evergreens, and I urged the removal of the old deciduous trees. My employer urged the mistake, but the lady voted with me, and of course we conquered. The trees were removed—what a blank! But it would never do to own that it was not the exact effect foreseen and desired.

The evergreens were planted, and everything done to ensure their success. They did succeed, and are fine now.

After ten years of the best labour I could give, and a farther absence of a like term, I visited the "old place." My "old master" gave me an unusual welcome by compelling me to dine at his family table in words that I am not likely to forget in consequence of their pleasantness and also their bitter sting. "You served me well," said he, "and successfully, and I treat you as I treat all good servants. The shrubs which you planted are all that I can desire of them, but I would give you a thousand pounds to bring me back my old trees."

It is quite clear now that my youthful improvement was in reality a mistake. I have reason therefore by that as well as other instances which I can adduce to say, Do not lightly sacrifice old trees or lightly value old friends.

I have also made mistakes when essaying improvements in dealing with old fruit trees, and seen similar mistakes made by others. These I will quote on a future occasion as a warning to those of advanced proclivities—a check to high-pressure energies.

I never now hastily destroy a tree. My first thought is renovation, my last destruction. There is a wonderful store of energy in an old tree as there is a fund of information and refreshing pleasantry in an old friend. Let us use them, and they will yet yield us profit.

But are we never to destroy? Yes, but destroy only to replace.—RADICAL CONSERVATIVE.

## THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 7.

It may be as well to remind the reader of the peculiar position which some of the market gardens of London occupied (I do not mean topographically, but with regard to the vending of the vegetables and fruit they produced) say a century and a half or two centuries ago. Greengrocers as we know them now did not then exist, London citizens procured their vegetables in one or two markets, or else from chance dealers in the streets, the early costermongers. Sometimes they chose to obtain garden produce for themselves direct from the grounds, and also to eat it on the spot; so that sundry of the market gardens were also at first pleasure gardens, until by degrees most of the land given to the culture of vegetables was devoted to recreative purposes, and the market gardens removed farther a-field, where there was more space at command and an atmosphere less defiled with smoke. That part of Surrey skirting the Thames which we call the district of Lambeth proper is not at present a particularly attractive spot; there is this connection, however, between the past and the present, that the place is still humid, and having a soil of pale clay it is likely to remain so. Etymologists, indeed, hint that the name itself is expressive of dirt or mire, coming from *lam*, and *hyd* or *hythe*, equivalent, therefore, to the "Dirt Haven," though Dr. Ducarel, the friend of Tradescant the gardener of Stuart times and a resident in Lambeth, will not have it, and insists that the *lam* should be *lamb*. But no good explanation of that name can be given, for it does not appear to have been pasture ground.

If we look back to Lambeth in the days when the early botanists found such plants as *Anchusa sempervirens* and *Epilobium roseum* growing there we see it intersected by many little paths, which are shaded with Willows, and along which stroll parties of Londoners on summer evenings; while on several patches of ground, which are slightly elevated (since much of Lambeth is so marshy that it is overflowed by a tide rather higher than usual), vegetables are cultivated for the market. The cost of carriage is not an important item, the produce being boated across the Thames, and usually landed at what was called "Strand Bridge," properly a pier, above which there was swung a bridge crossing the lane leading from the landing-place into the Strand. The "*Sparagus Garden*" at Lambeth forms a subject of comment in an old play, thus letting us know incidentally that this plant was cultivated there with success, and it would seem the Londoners were particularly fond of this vegetable.

Vine Street, Lambeth, is not only of interest to the antiquarian as denoting the locality of a very ancient roadway, it is also notable because it is said by an old tradition of the neighbourhood to have had vineyards along it a few centuries back. A writer on the history of Surrey, when mentioning this circumstance, takes occasion to say that our forefathers cultivated Vines more for shade and ornament than use, because it was not likely they had Grapes when the climate was more moist and variable than at present. I venture to differ from him. Possibly unlike the fox in the familiar fable, people in the olden time had no objection to sour Grapes, but I do not think they would have grown Vines without obtaining a return of fruit; and we read in various authors about the manufacture of wine from English Grapes. Nor is the statement about the English climate quite correct. Could it ever have been more variable? I fancy not, and there is evidence tending to show that the summers were longer and hotter.

Passing by the Apollo Gardens, Lambeth, and the Mount Gardens, both of dubious history, I should next notice Cuper's Gardens; because, though afterwards the spot became a notorious place of public entertainment, in the first instance there really was a garden in the charge of one Boydell Cuper, who was a dependant of Thomas Howard, Earl of Arundel, whose fame is prolonged by the Arundelian marbles. These gardens were nearly opposite Somerset House, and as Aubrey speaks of the fine walks there were in his time, it is supposable that the earl planted the ground with some care and taste, though it is not probable he put in many exotics. Subsequently the estate came into the hands of one of the Oxford colleges, but the gardener of the late earl, by some means or other, became tenant, and removed here sundry fragments of Greek and Roman marbles he had obtained, turning it into a popular resort, which, by accident or joke, was often called Cupid's Gardens, and finally closed in 1753.

Before leaving this part of Lambeth it should be remembered that some of the Archbishops of Canterbury took much pleasure in plant or tree culture, and visitors from other countries occasionally sought permission to view the nursery and kitchen gardens attached to the palace. Two venerable Fig trees, presumed to have been planted by Cardinal Pole, were objects of special remark until they succumbed with old age. Scions, however, taken from them were flourishing not many years ago, and are probably living still. Archbishop Cornwallis seems to have been one of those rather partial to gardening in the eighteenth century. Oldys, in his casual observations on fruit trees, does not forget to expatiate on the splendid Mulberry trees he saw in July, 1753, in the gardens of Carlisle House, Lambeth Marsh. He computes the shade of one of these as covering 40 yards. It was named after Queen Elizabeth.

The monument erected at St. Mary's, Lambeth, to the memory of the Tradescants has been seen by a great many persons doubtless, yet by few horticulturists I imagine, though men who, as one biographer puts it, "introduced botany to this country," are surely worthy of much honour. The Tradescants, or as their neighbours called them, the "Tradescins," by a slight distortion, were of Flemish descent, and arrived in England at some period in the reign of Queen Elizabeth. There must have been something very remarkable about them, for we read that "they travelled art and nature through"—a surprising journey! Quaint also are these allegorical but ungrammatical lines:—

"These famous antiquarians that had been  
Both gardeners to the Rose and Lily Queen,  
Transplanted now themselves, sleep here, and when  
Angels shall with their trumpets waken men,  
And fire shall purge the world, these hence shall rise  
And change this garden to a paradise."

Is an allusion here made to the churchyard or to the actual garden of the Tradescants? That was in South Lambeth; on the assertion of Peter Cunningham we have it that the Nine Elms Brewery occupies the site, a woeful descent from the beauties of Flora. A house, subsequently called Turrit House, was occupied by Tradescant the younger, if not by his father before him; it was situate in the South Lambeth Road. The physic or nursery garden could not have been of any considerable extent, though Tradescant the younger deemed it worthy of having a printed catalogue of the plants it contained, which was published in 1656. How John Tradescant, sen., acquired this property is uncertain. That he must have been well connected is clear from his having the title of gardener (honorary?) to Charles I. One of the most remarkable achievements

attributed to him was his obtaining the Apricot from Algiers at the risk of his life and property as well, though we have not the exact details. In his travels he obtained a variety of slips and seeds, and deposited them in his South Lambeth garden, and his son followed his example, visiting America, which does not appear to have been honoured by the presence of the elder Tradescant, despite the assertion about the wide range of his travels. At some date in 1749 the Royal Society paid a formal visit of inspection to this plot of ground, but could not discover more than a dozen or so of trees that they thought themselves justified in attributing to one or other of the Tradescants. And that there should not be lacking the sombre side in the history of this garden, it is stated that when John Tradescant, jun., died in the reign of Charles II., he left to Elias Ashmole the antiquary his miscellaneous gathering of curiosities, and about these there arose a litigation. This with other unfortunate circumstances so affected his widow that she drowned herself in a pond on her premises in 1677; and as the epitaph at Lambeth records the previous death of her son, I presume this branch of the Tradescants thus became extinct.

In No. 454 of the "Spectator" this curious passage occurs:—"I landed with ten sail of Apricot boats at Strand Bridge, after having put in at Nine Elms, and taken in Melons consigned to Mr. Cuffe of that place to Sarah Sewell and Company at their stall in Covent Garden." This points to a largish production of Apricots in the early part of last century, if the incident is not imaginary. As for Mr. Cuffe, we might never have heard of him had he not been embalmed in the pages of the great British essayist. Where he grew Melons at Nine Elms is quite as uncertain as is the identification of the planter of the nine Elms that gave name to the district. Doubtless Melons would succeed well in a locality then quite as watery as Lambeth, and not much better now. Old Vauxhall was not, I believe, ever a market garden, though an antique print shows beside it several strips of land with growing Cabbages and other vegetables. There were small market gardeners herabouts when Vauxhall was in the height of its popularity in the days of Tyas, who with all his energy and perseverance had a melancholy way of looking at things, and was decidedly unfortunate in his weather on *fête* days. As the tale goes, when some special affair was coming off, one of his horticultural neighbours came up to him with a face expressing anxiety, wishing to know if the night was positively fixed. Tyas told him, but as he walked off called him back to inquire why he was so earnest about it. "Why?" said the gardener, "Because I mean to choose that day to sow seeds, for it will be sure to rain in the evening."—C.

## HARDWICK HALL.

THE SEAT OF THE MARQUIS OF HARTINGTON, M.P.

At the distance of two miles from the main road leading from Chesterfield to Mansfield stands the celebrated mansion of Hardwick Hall, the seat of the Marquis of Hartington. It is situated on a gentle eminence 594 feet above the level of the sea, in the midst of a finely wooded and undulating park of 744 acres, in which are many venerable Oaks, probably indicating that it once formed a part of the forest of Sherwood. The mansion was built in the reign of Queen Elizabeth by the Countess of Shrewsbury, the third daughter, and after her husband's death the co-heiress, of John Hardwick, Esq., who brought this estate to her second husband Sir William Cavendish, from whom it has descended to the present noble owner.

The Hall, which is in every essential part just as the Countess left it, was commenced about the year 1576. It is of striking proportions, the length being 210 feet, the width 100 feet, and the height 98 feet. The windows are so large and numerous as to have given rise to the saying in the neighbourhood—

"Hardwick Hall,  
More glass than wall."

And the six towers with which it is crowned are surmounted by open parapets of stone, in which occur the oft-repeated initials "E. S."

The flower garden before the west front, immediately opposite the mansion, is surrounded by a wall with quaint ornaments of stone, and is entered from the park by large doors between two picturesque lodges; and horticulture, like architecture, is made to do homage to the memory of E. S., these initials

being preserved in carefully cultivated verdure and flowers. A long pavement leads to the great hall, wherein everything is in keeping with the external appearance of the house. It is hung with tapestry; and the dark oak wainscot throws out into relief a fine statue in Maltese stone of Mary Queen of Scots, on the base of which is inscribed—

"Mary Queen of Scots, born 1542.  
Driven into exile by her own subjects, 1563.  
Put to death by her hostess, 1567."

A pair of elk's horns, found in a bog in Ireland, and branching out to a width of 9 feet, adorn the walls. Ascending a wide stone staircase you enter the chapel, where the chairs and cushions are covered with ancient needlework, and the walls with painted tapestry depicting subjects of Scripture history—viz., the conversion of St. Paul, the punishment of Elymas

the Sorerer, St. Paul pleading before Agrippa, and his shipwreck at Melita.

The dining-room is wainscotted to a considerable height, and hung above with family portraits, among them being the builder of the house and her second husband, and the beautiful Duchess of Devonshire, by Sir Joshua Reynolds; and over the chimney-piece is this inscription:—"The conclusion of all things is to fear God and keep his commandments.—E. S. 1597." The drawing-room is also wainscotted and hung with ancient tapestry representing the story of Esther and Ahasuerus; and here are many valuable pictures, especially one of Arabella Stuart, who spent her early days at Hardwick with the Countess of Shrewsbury. On the grand staircase leading to the state apartments is some very fine tapestry, part of which, judging from the costume of the figures, is probably of a date anterior to 1428, the date of the tapestry

Fig. 120.—HARDWICK HALL.

in the long gallery. The presence chamber is of fine proportions, the walls being partly covered with tapestry which depicts scenes in the history of Ulysses, and with partly plaster ornamentation peculiar to the Elizabethan period. The furniture is of the same period, consisting of cabinets and tables and chairs from the old house, and deserving of particular attention. A door leads out of this room into the library, from the windows of which a charming view is obtained of the ruins of the other house and the western flower garden, and further on is the Queen of Scots' apartments, containing a bed, the hangings of which are said to have been worked by the Royal captive.

The picture gallery, which is 169 feet long, 122 feet wide, and 26 feet high, is hung with ancient tapestry and covered with portraits of the family of the noble owner, and of many other celebrated characters. Among the most interesting are those of Henry VIII., Queen Elizabeth and Mary Queen of Scots, Cardinal Pole, Bishop Gardiner, the Countess of Shrewsbury, her husband Sir William Cavendish, the first Earl of Devonshire, and Thomas Hobbes; which with many others—as appears from an inventory of the pictures in the possession of Lady Shrewsbury—once adorned the walls of the older house. A flight of steps made of solid oak leads up to the roof, which is covered with lead, and commands a most extensive and varied view of the beautiful park and surround-

ing neighbourhood. Far away towards the west are seen the distant hills of the Peak of Derbyshire, and on the eastern side of the house the eye wanders over a richly wooded plain in the counties of Nottingham and Lincoln.

At a stone's throw from the present house stands the ruins of the old Hall, in which the Countess of Shrewsbury lived and died, and where the philosopher Hobbes breathed his last. Unfortunately a great portion of this building was taken down in the reign of William III., and desolate are the remains of this once noble pile. The giants' chamber, however, so called from two colossal figures over the chimney-piece, still exists, and is of such beautiful proportions as to have been thought fit for the pattern of a room in the Palace of Blenheim. Other rooms there are almost entire, having ornamental chimney-pieces, and the windows of which command extensive views of the surrounding country; but they are fast falling into decay, and the ruins of this magnificent house once occupied by the great and noble of the land are tenanted by the owls and bats, which haunt the Ivy now covering in great luxuriance the walls of its deserted chambers.

The park to which we have already referred is remarkable for its fine old Oaks. One we measured, and it had a bole 80 feet in circumference at the height of 5 feet from the ground. During the last few years many improvements have been made by J. G. Cottingham, Esq., agent to the Duke of Devon-

shire and the Marquis of Hartington, consisting chiefly of new plantations and groups of trees so judiciously placed as to render the park one of the most picturesque in the county of Derby. Mr. Cottingham has also ever been anxious to promote the comfort and meet the wishes of the numerous visitors to Hardwick, and he has done much for the general benefit of the place.

As soon as the visitor is within the precincts of the western court he at once perceives that everything harmonises with the architectural arrangements of the mansion. A broad herbaceous border runs along the end and down one side of the court, while on the other side is a Yew hedge 8 feet in height, so shaped as to form a continuation of the coping of the wall. The flower beds are out out in the turf, the letters "E. S." being conspicuous among them. A plan of the flower garden will be given next week, when the reader will have an idea of the style of bedding which prevails at Hardwick, and which is so arranged as to present perfect sheets of the most varied and brilliant colours. The two grand Cedars of Lebanon at each side of the entrance gates were planted forty years ago.

Leaving the west garden by a side door the visitor enters an enclosure of eight acres on the south side of the mansion, which has been laid out in the ancient style by the Lady Louisa C. Egerton. It is divided into four parts by avenues of Yew and Hornbeam hedges running north and south and east and west, the grass walks between them being 20 feet wide and in excellent condition. The first part contains the croquet ground, surrounded by fine evergreens and Conifers, and amongst them will be found a handsome Cupressus macrocarpa, Wellingtonias from 30 to 40 feet high, fine Silver and Golden variegated Hollies, Austrian Pines, Evergreen Oaks, grand old Yews, and ancient Walnuts, the trunks of which average about 15 feet each in circumference. The second part, which is in close proximity to the house, is a fruit orchard, and Apples, Pears, and Plums are well represented. The third is chiefly taken up with Filberts and other fruit trees; and the fourth is entirely devoted to vegetables. Mr. E. Wilson is the gardener, and, as might be expected from his training at Chatsworth, is a thoroughly practical man. His skill and taste are evidenced in every part of the gardens at Hardwick, and the visitor will notice in the herbaceous border 200 yards long a collection of plants and flowers which is hardly to be equalled by any other in the United Kingdom.

The Hall and grounds at Hardwick are thrown open to the public, who come to them in great numbers during the summer months from Sheffield and other neighbouring towns and villages; and we can hardly picture to ourselves a prettier sight than the one afforded by those who, at other times seldom out of the sound of the rumble of machinery, are now wandering through the quiet groves of Hardwick, or sitting down on the green turf to enjoy the social meal; and we believe that the privilege thus accorded to the public by the liberality of the noble owner is gratefully appreciated, and tends not a little to lead multitudes to forget the cares and anxieties of arduous toil in the pleasure they derive from visiting, though for so brief a period, "this scene of other days."

### NIPPING FROSTS AND TENDER PLANTS.

WHATEVER difference of opinion there may be among the scientists as to the way in which frost acts injuriously on plants, there is none whatever among practical men as to its disorganising and destructive agency. It does not matter to him whether disorganisation and death are brought about by rupture of the cells, consequent on the congelation of the enclosed fluids, or rather, as some think, by the congelation of that which permeates the intercellular spaces; the practical fact is all the same. The winter brings its nipping frost, and susceptible subjects, if unprepared for, are caught and either killed outright or maimed. No one ought to cherish the advice of the gentle Mantuan more kindly and pray for mild winters than the gardener; for the fine talk with regard to "seasonable weather," the snow taking away the cold, purifying the air, and all that—severe winters, such as we just have had a sharp inkling of, are unquestionably notorious for running up the death-rate both of men and plants. In both cases this may unquestionably be largely modified by means of precautionary and remedial measures, if judiciously availed of. To some of these, as regards plant life, we now purpose to allude, with a view to throw out a few useful hints, as also to anticipate the inquiries of correspondents.

With regard to preventive measures, there is none more important than, in the first instance, trying by all means to secure, as much as may be, firmness and ripeness of newly-formed growths previous to the resting or winter period. Next, it is of importance that, in the absence of demand, the supply of moisture at the roots should be greatly reduced, and the soil kept on the side of dryness rather than otherwise—just moist, neither wet nor saturated. Having the foliage of house plants dry when frost is anticipated, and keeping it so during its continuance, is a point not to be lost sight of. Surfacing over the soil with dry moss or other light material, or placing the pots in which the plants are growing within others of a size or two larger, so as to retain a stratum of air between, are aids not to be despised. With regard to external measures for protection, it should be borne in mind that the great point is to prevent radiation, and the glass, that universal plant protector, is one of the most efficient of radiators. This being the case, it will be well to bear in mind that if, with a view to guard against the effects of frosts, recourse is had to external covering of glazed structures, such covering should not be of a kind or so placed as to be a most efficient conductor of heat instead of preventing its radiation. Therefore such coverings, if of matting or textile fabrics, should always be so arranged as to keep them from actual contact with the glass, and allow of an inch or so stratum of air between them and the glass, which stratum of air will be as a warm blanket and most potent protecting agent. It is in this way that double-glazed houses are so efficient in reducing risk to plants and lessening the consumption of coal. Where other and extemporised coverings are availed of, they should be always such as will not lie closely or solidly, but rest elastic and lightly on the glass, with air filling their every interspace, such as dry hay or straw, dry leaves, moss, or fern. It will be well to bear in mind that vegetable tissues may be actually frozen and yet come again all right, provided a rapid thaw is guarded against, and the normal condition allowed gradually to come about.

We have a familiar instance of this in the case of pitted Potatoes. If after frost sufficiently severe to reach them, the pit be opened and the tubers suddenly exposed, they are done for. If, on the other hand, the pit be allowed to remain intact and not disturbed for some time, no harm is done, and the tubers come out in good condition. This will explain why it is autumn-planted Potatoes come safely through, and that we so often see among corn succeeding Potatoes fine healthy plants of the latter growing from tubers which chanced to remain in the ground with perhaps very little, or scarcely any, depth of soil to protect them from frost. Here we have a lesson never to expose frozen plants suddenly to artificial heat, sunshine, or light. When the action of frost on soft, succulent, free-growing plants, such as Cinerarias, Calceolarias, and the like is inconsiderable, and there is no disorganisation of the tissues, placing them in shade and syringing with cold water are familiar and successful agents in restoring frost-bitten subjects. Fearing that we may not have yet seen the worst of the present winter, and that sharp frosts and anxious hours are yet before us, we have thought it not unseasonable to throw out these few hints with regard to preventing or modifying the injurious effects of the plantsman's dread—the nipping frost.—(*Irish Farmers' Gazette*.)

### NOTES ON VILLA AND SUBURBAN GARDENING.

**CAMELLIAS.**—One of the most sought-for flowers at this season of the year is the Camellia. For the decoration of the greenhouse it is a gem, and those who attend balls and other parties so prevalent at this time are not willing to go without a flower if it can be obtained. Many an amateur will grow a Camellia where he might grow other plants with less trouble and more certainty of plenty of bloom. The fact is that the plant is estimated by many to be able to take care of itself, being supposed to be of that hardy nature as to be sure to flower when the time comes round. This is wrong, for the Camellia needs as much attention as any other plant. There are seasons when it will apparently do without the attention that other plants require, but it is only when the preliminary treatment has been good.

The Camellia is a plant which ought to have a good foundation laid at the beginning, whether it be grown in a pot or tub, or planted out. For pot-culture the one-shift system is the best, which obviates repotting every year; but for this system effectual drainage must be provided and good soil. The latter might consist of rich loam of a turfy nature, and sufficient sand to make it open; this will last a long time and support the plant well. I have often thought that the best way of growing

Camellias is by planting them out; they are not very vigorous-rooting plants, and they are better let alone after being properly placed; and it is astonishing what a small place a plant requires in regard to rooting space, but it must be abundantly supplied with water—in fact, if the plants are rooting well they can scarcely have too much in the ordinary way of watering. It is not often that a plant in vigorous health casts its buds—a circumstance so prevalent about here this season.

The plan of turning the plants outdoors after the growth is made is a matter that needs more care and attention than is usually given. Wherever they are placed the pots ought to be plunged or protected from the sun in some way. The roots being so fleshy and so fond of moisture, any neglect in watering with a fierce sun playing upon the pots does more injury than many people imagine, and it is these sort of checks with an irregular course of treatment that causes the buds to drop.

Camellias are plants that require a very even temperature, and at no time require much heat; but during the time they are making their growth—that is, after the bloom is over, they require most, and not at that time more than 60°. They like moisture overhead at most times, and especially when making new growths. After the growth is made particular care is necessary that the plants are not turned outdoors too soon, for this is a most dangerous time, as the sudden transition from the even temperature of the house to the variable temperature outdoors, perhaps one hour cold and the other warm, does an amount of mischief which cannot be remedied at no time during the season, and is one of the principal causes of the Camellia falling into bad health, and when that is so these are among the most difficult of plants to bring round.—THOMAS RACORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

We have been digging vacant ground and borders for early Peas and Potatoes. The borders for Peas ought to have been dug in October or early in November; for it does not give the Peas the best chance to flourish if sown in a week or so after the ground has been dug, unless it should be dry, which is not the case this season. When the ground is wet at the time of drawing the drills there is usually some dry material that has been turned out of the potting-shed, or, what is better, the surface soil from inside Vine borders that has been removed to allow of fresh dressing; this is used to fill up the drill instead of the wet surface soil of the border. The Peas are sown in drills across the border 3 feet apart, and we sow thicker at this season than we do later, when the seed is not so liable to accidents. Should the weather continue favourable the Peas will be sown before this is in the hands of the printers. It is necessary to tread as little upon the ground as possible when it is wet. Rather than tread upon the ground we have a few boards laid down to tread upon when drawing the drills. There is some difference of opinion about manuring the ground for Peas. There are some who grow fields of Peas in this neighbourhood for market purposes, and they seldom apply manure for Peas, but they are usually sown on ground that has been heavily manured for the previous crop. Our ground is always manured for the first crop, and we prefer to trench the manure in. If this is not done it is dug-in deeply. The varieties that are sown now for the earliest crops never grow too much straw. We shall trust entirely to the two early varieties of Mr. Laxton's—William I. and Alpha; they are both blue Peas, the latter is a trifle later than the other, and is a wrinkled Marrow. With the above will be sown a few rows of Dr. Hogg for comparison. It was tried last year with the later crops, and our impression is that this is the best Pea that Mr. Laxton has yet sent out to the public.

We shall also place single layers of the early Potatoes in shallow boxes in the course of a few days, just covering the tubers with cocoa-nut fibre refuse. They are now lying in a dry loft and are sprouting. If they were left where they are for a month or six weeks the sprouts would be drawn-up weakly, and would have to be removed at the time of planting. We shall place the boxes in the cool orchard house as near the glass as possible; the tubers will in such a position sprout more slowly, and will be strong plants at the time they can be transferred to the border. Those who can command glass lights or any of the numerous glass protectors are fortunate, and ought to use them for their early Peas and Potatoes on the wall borders.

Cauliflower plants under handlights are doing very well this season. The lights are removed every day while the weather continues mild. Of course the plants are kept clean, and slugs are destroyed if there is any trace of them on the plants. We have other plants under glass frames which will be planted out early in March if the weather is favourable. In a cottager's garden close to us may be seen a healthy lot of Cauliflower plants, and the owner of them seldom fails to have Cauliflowers in almost as early as we do, and at that time the heads com-

mand a good price in the market. He has no glass, but puts his plants out under the shelter of a low bank facing south. He has some short litter at hand to throw over them in severe frost. The worst enemy to them seemed to be the slugs, to which the old bank and litter affords shelter. Sow Mustard and Cress in boxes, to be placed in vineries or anywhere where there is a little heat.

### PINE HOUSES.

It does not seem to be universally believed that to grow Pines successfully there ought to be three compartments which can be heated separately. We know a gentleman who thought that in one house Vines and Pines, Cucumbers and Melons, could be tolerably well grown. It would be possible for such a miscellaneous collection to exist together, but none of them would give satisfaction, and those who wish to grow Pines well must have three houses—the fruiting house for established plants, which ought to be the largest; next to it in size should be the succession house for intermediate plants; and a smaller house or lean-to pit for crowns and suckers. The suckers which were potted early in September last year are still at rest, and will not be started for two or three weeks. The lean-to pit cannot be heated above 50° in cold weather, but we can command 55° except in very severe frost. The other houses are also at rest, and the temperature is from 55° to 60° at night, or it may be 65° when the weather is mild. The higher temperature will not unduly excite the plants if the hot-water pipes are only moderately warm. A number of fruits in the fruiting house are swelling nicely with a low night temperature, say 55° to 60°. Smooth-leaved Cayennes that have thrown up early in December have not been ripe until the following June, but the fruit has been of good quality, and has carried off first prizes at the London shows in that month. The temperature of the tan beds is about 80° or 85°.

### CUCUMBER HOUSE.

The occupants of this structure will not continue in health if considerable care is not taken both in ventilating the house and in applying the proper amount of heat and atmospheric moisture. Fresh air must be admitted every day by opening the top ventilators a little, unless the weather is unusually severe. Our house is kept at 65° at night, with an increase of from 5° to 10° by day. Then as to atmospheric moisture, one cannot give instructions about this unless the heating power of the pipes is taken into account. If it is necessary to heat the pipes very much to raise the required temperature, then it will be necessary to sprinkle water about very frequently; when it is not necessary to heat the apparatus so much, less moisture in the atmosphere will be required. The growths ought not to be allowed to become crowded.

### PEACH HOUSE.

It is now a good time to start the early Peach house. Of course the trees have been pruned and the branches trained to the wires. The inside borders should have a thorough watering. In previous numbers it has been stated that the Peach-house border should not be allowed to become dust-dry. The night temperature should not be above 50° from artificial heat; 45° will be high enough at first. The trees in later houses that have not yet received any attention should be pruned; in doing so save the moderately strong wood, cutting out entirely the most vigorous shoots. All the young wood that is furnished with single blossom buds will have a leaf bud at the end; such must not be cut back unless there should be a triple bud on the shoot, the centre one of which is sure to be a leaf bud, which will form a leader to the branch for next year.

### PLANT STOVE AND ORCHID HOUSES.

There is now a goodly display of flowering plants to be obtained in the stove, although many that were in flower a month ago are still in beauty. The different varieties of Epiphyllum are very showy and most distinct in character. Small plants struck from cuttings, and potted in 60-sized pots, are arranged on the outer edge of the stages, and very pretty they are with the richly-coloured flowers clustering on the pendant growths which hang over the sides of the pots. Standards 1, 2, or 3 feet high are very effective when placed with the stems rising through an undergrowth of the dwarfier species of exotic Ferns. A very useful old plant which we also have in plenty at this season is the *Thyracanthus rutilans*. It is very easily grown from cuttings, which make large flowering plants the first season. The pendant panicles of red flowers have a very novel effect. Very useful both for decorative purposes and for cut flowers is the *Euphorbia jacquiniiflora*. It has also the merit of being easily cultivated, and forms nice flowering plants in the winter from cuttings of the previous spring. *Eranthemum pulchellum* is also a very beautiful and distinct stove plant; its intense blue flowers are closely arranged on short terminal spikes, and are abundantly produced. It is one of the easiest cultivated plants we have, and strikes freely from cuttings.

We fumigate the houses frequently to destroy thrips. The plants at this season will not be injured by as much smoke as will kill the insects. Washing with strong soapy water is recommended to kill thrips. It will do this if the insect can be

touched with the water; but this cannot always be done, and we know that frequent fumigations at this season will destroy the pest. Mealy bug is equally troublesome; tobacco smoke does not annoy it much. The only sure way to rid the house of it is to watch the plants every day or two, and destroy every insect that can be found, either by washing, or if the plants are not much infested with it, the bug may be picked-off by hand.

#### FLOWER GARDEN.

Since the snow with the accompanying frosts have disappeared, the ground has been so wet that it has not been possible to wheel barrows over the walks or to tread on borders with the feet. As soon as the surface is a little hardened by frost the Roses will be mulched with rotted manure. The lawn is swept and rolled about once a week or ten days. The grass has a rough uneven appearance in winter when this is not done. It should neither be rolled nor swept during frosty weather. If a roller is passed over grass when it is crisp with frost the blades of the grass are broken, and when the thaw comes the decaying grass is very unsightly.

Bedding plants are looked over occasionally, and all decaying leaves picked off. Zonal Pelargoniums of the tri-color and variegated section were potted-off in September and October. The more hardy green-leaved sorts will now be potted as soon as possible. Auriculas are looked over about once a week; the leaves are decaying rapidly, and have frequently to be removed. They cause mould and decay in the stems sometimes if their removal is neglected. Carnations and Picotees in frames are remarkably strong and healthy this year. The lights are removed entirely on fine days, and they require but little water at the roots. Pinks have to be pressed into the ground after frost, by applying the fingers of each hand round the roots.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

WESTMINSTER AQUARIUM. April 18th and 18th, May 10th and 11th, May 30th and 31st, July 5th and 6th, October 4th and 5th.  
MAIDSTONE (Roses). June 21st. Mr. Hubert Bensted, Rockstow, Maidstone, Sec.  
SPALDING. June 21st. Mr. G. Kingston, Sec.  
SOUTHPORT. July 6th, 7th, and 8th. Mr. E. Martin, Sec.  
HELENSBURGH (Roses). July 12th and 18th. Mr. J. Mitchell, Sec.  
DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.

### TRADE CATALOGUES RECEIVED.

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea.—*Catalogue of Kitchen Garden and Flower Seeds, Implements, &c.*

Sutton & Sons, Reading.—*Illustrated Amateur's Guide and Spring Catalogue.*

James Carter & Co., 287 and 288, High Holborn, London.—*Illustrated Vade Mecum and General Seed Catalogue.*

William Paul & Son, Waltham Cross, London, N.—*General Seed Catalogue.*

James Vick, Dorchester, N.Y.—*Illustrated Floral Guide and General Seed Catalogue.*

Dicksons & Co., 1, Waterloo Place, Edinburgh.—*Descriptive List of Gladioli.*

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (A. W.).—"Keane's In-door Gardening" may be had from our office if you enclose twenty postage stamps and address.

AMERICAN BLIGHT (S. S.).—The Rev. Mr. Badlyffe states:—"The quantity of salt is not of particular consequence; a couple of double handfuls in a stable bucket of fresh slaked lime-water would be sufficient. I believe the lime without the salt would destroy the blight. Lichens or moss on the trees greatly favours the blight and also stop-up the stomata of the skin. Lime-and-salt wash will destroy them and cleanse the trees."

OYSTER SHELLS (W., Kensington).—Whether calcined or bruised they must be prepared at home. In a furnace they are easily burned, and in a chemist's large iron mortar they are easily pounded.

CONTINUOUS CROPPING (M. A. H. B. L.).—Lettuce sown in March or early in April would be off early in July; but as that is too late for sowing Veitch's Perfection Pea, you may at the early part of June remove every fourth row

of Lettuce, they being in rows a foot apart, and sow the Peas in the place of the Lettuce. The Peas will be ready in September, and may be cleared off by the first or second week in October, when you could plant Lettuce to stand the winter in the ground after the Peas, the Lettuce being sown the third week in August. Lettuce and Radish may be followed by Celery, but the Celery would not be off in time to be again followed by Lettuce. Cabbage planted after the Lettuce and Radish would be off at the end of September or early in October, and might be followed by Lettuce transplanted. The best summer Lettuce is Paris White Cos; Kiah's Hardy White Cos is also excellent.

ANNUALS FOR CUT FLOWERS (Idem).—"Agrostis Imperial Dwarf, Chrysanthemum carinatum Dunnettii flore-pleno, C. carinatum Dunnettii, double golden; Centaurea cyanus major, "Delphinium French hybrids (if sown early they will flower the same season though they are perennials); Heliopsis monstrosum varieties, particularly useful for dried flowers for winter bouquets; Leptocarpus densiflorus albus, Mignonette Large-flowered pyramidal, Sweet Pea in various colours, Scabious dwarf, Sweet Sultan, purple, white, and yellow; "Ten-week Stocks, "Phlox Drummondii var., "Aster Dwarf Bouquet. Those marked with an asterisk require to be sown in a hotbed in March, and the plants pricked off an inch apart in pans or boxes when large enough to handle, and grown-on in gentle heat, hardening well off and planting out in May.

PIPING REQUIRED FOR WARM STOVE (Nat., Reading).—One-foot run of 4-inch pipe, or 1-foot superficial of heated surface, is not sufficient to heat and maintain 15 cubic feet of air to a stove temperature; 2 feet should be the minimum of piping to heat to a warm stove temperature 15 cubic feet of air, and with double glazing this amount of piping will be sufficient, as the temperature will be less liable to cool than in the case with single glazing. It is a great mistake to restrict the piping, for when that is the case the heated surface requires to be kept at a high temperature, and the furnace to maintain it needs to have in it a fire in a high state of combustion, and the greater the fire the greater will be the velocity of the heat in the direction of the chimney, more fuel being required and a greater proportion of the heat generated escaping by the chimney.

LIQUID MANURE FOR AZALAEAS (Idem).—These and other hardwooded plants growing in peat soil do not require liquid manure, or only in a very weak state, and the best for them is one peck of soot and fresh cow dung mixed with sixty gallons of water, and applied twice a week during growth, or when the plants are advancing for flowering, the pots being full of roots. Except in experienced hands the application of liquid manure to hardwooded plants is best omitted, as its injudicious use is often attended with disastrous consequences.

AMMONIACAL LIQUOR FOR DESTROYING WEEDS ON WALKS (J. R.).—It will certainly kill most of the weeds when applied at full strength, or cause them to be very much browned, yet from the high fertilising character of the liquid the weeds will grow considerably stronger the following season. Besides, it is a great waste of manure, the ammoniacal liquor being valuable for watering during growth diluted with sixteen parts of water, especially vegetable crops; and applied at half the dilution, or one pint to a gallon of water, at the time of sowing or planting, it is a good preventive of insect pests and a valuable fertilizer for the crops. If you apply it for destroying weeds, do so in dry weather in April. A better remedy for weeds on walks is to dissolve 1 lb. of powdered arsenic in three gallons of cold water, boil, and keep stirring; then add seven gallons of cold water and 2 lbs. of crushed soda; stir the whole well whilst boiling, and with a rose watering-pot apply to the walks in dry weather, from March to May inclusive being the best time. The above quantity will be enough for 25 square yards. An inclining board should be placed at the sides of the walks or grass to keep off the hot liquid.

DESTROYING ANTS ON LAWN (W. S. B.).—We were once greatly troubled with ants, but now are remarkably free of these troublesome pests. For the past three seasons we have had penned near the lawn hens, foster parents to young pheasants, and it is certain the ants have become very scarce. A hen in a coop with a brood of chickens would no doubt answer as well, the coop being placed near the nests or haunts of the ants, moving it as circumstances require. Guano sprinkled over the nests will drive the ants away, and arsenic mixed with treacle and smeared on pieces of tile or slate will destroy all that partake of it, but great care is required to be taken in the use of this virulent poison.

RAINING PLANTS FROM SEED FOR ROCKWORK (Idem).—*Alyssum saxatile compactum*, *Antennaria dioica minor*, *Arabis alpina*, *Anthriscus gracilis*, *A. purpurea grandiflora*, *Campanula carpatia*, *C. carpatia alba*, *Dianthus neglectus*, *Ericus alpinus*, *Saxifraga aizoon minor*, *S. Cymbalaria*, *S. longifolia*, *Silene caucasicola*, *S. Schaffa*, and *Veronica saxatilis* and *V. prostrata* are suitable. Seed should be sown in April in pots or pans well drained, and filled with a compost of turfy loam and sandy peat in equal proportions, with a fourth each of leaf soil and silver sand, the compost sifted, and the surface of the pots or pans made very fine and smooth, and well watered, standing for a few hours, then water again, and when the water is soaked in scatter the seed evenly over the surface and just cover it with very fine soil. The pots or pans should be placed in a sheltered position, and so that the sun does not fall upon them from 8 A.M. to 5 P.M., or shade from the sun for that period, the main point being to keep moist without having to resort to frequent waterings. When the young plants are large enough to handle prick out in pans prepared as for the seedlings about an inch apart, treating similarly, and before they become crowded plant in the rockwork, shading until established. Seeds of rock plants are not in given kinds always procurable, hence we advise you to procure a collection of half a dozen or a dozen kinds as you may wish, stipulating for good free-growing hardy kinds.

GREENHOUSE FLOWERS LOSING COLOUR (A. B.).—The loss of colour is the result of the plants being grown at a distance from the glass, and not having light sufficient to bring out the high colour, with probably a deficiency of heat and moisture during the growing season. Afford a position near the glass, and a moister atmosphere and braker heat, with partial shade in very bright weather during growth, but full exposure after August. A temperature of 65°, rising to 80° or more from sun, is desirable when in growth, and 60° to 65° from fire heat when coming into bloom. A compost of turfy loam, sandy fibrous peat, and leaf soil, in equal parts, with a sixth each of silver sand and old cow dung, the whole well mixed, broken up rather small, but not sifted, will grow them well. Water moderately, not allowing the foliage to flag for lack of it, nor the soil to be soddened by too frequent waterings.

HEATING A SMALL GREENHOUSE (O. E. P.).—Had you been certain of a proper supply of gas we should, in preference to any other mode of heating, you having little time to spare—have advised you to have a gas-heated boiler

and 2-inch hot-water pipes, a flow and return, along the front and both ends or, if the piping may not be taken across the end of the house from the doorway, interfering with that arrangement, have piping in front or at back to make the quantity of piping required, which will, to exclude frost, require about 56 feet of 2-inch piping. Owing to the pressure of gas being not more than half after midnight, we should have a stove boiler, and fix it in the shed at the back of the greenhouse, having attached to it the quantity of 2-inch hot-water piping above named. A boiler of the kind named would not require very frequent attention.

**POULTRY DUNG (G. M.).**—It is applicable to all plants and crops that need manure. Containing much ammonia it must be used cautiously. An ounce to a gallon of water for potted plants. For kitchen-garden crops it may be applied an inch deep on the surface before digging.

**DESSERT PEARS FOR DUREM (A Northerner).**—Bourré Superfin, Oct.-Nov.; Doyenné du Comice, Nov.; Marchal de Cour, Nov.-Dec.; Marie Louise d'Uccle, Oct.-Nov.; Thompson's, Nov.-Dec.; Fondante de Charnes, Nov.-Dec.; Comte de Flandre, Dec.; Haeon's Incomparable, Dec.; Winter Nells, Dec.-Jan.; Bourré Bachelier, Jan.; Forelle, Jan.-Feb.; Bourré Sterckmans, Jan.-Feb.

**COAL TAR FOR FENCING (S. P. F.).**—Applying it at this season to the outer side of the fence would not injure trees on the inner side. We have some boarded fences dressed with Stockholm tar, and we have found it injure the leaves in summer when the sun melted the coating. You should only use a coping-board before the blossoms opened, and remove it again when the fruit is set. The small quantity of rain water from it would not injure the trees.

**PEARS FOR SUCCESSION (Idem).**—William I. is the best early. Add G. F. Wilson to the other two sorts you name.

**PLANTING BORDER FACING EAST (J. F. K.).**—We have a border in precisely the same position as yours; it is also sheltered by shrubs. Part of it has been planted with herbaceous plants, and the remainder with mixed bedding plants. Both have succeeded remarkably well. We trenched and manured the ground first, and the subsoil is well drained.

**NAMES OF FRUITS (L. L.).**—1, Blenheim Pippin; 2, Gravenstein; 3, Hollandbury; 4, Alfriston; the other two not known.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### POULTRY, PRESENT AND FUTURE.

It is said we can get used to anything in time, and we believe it; and although we can recollect some years ago at school we had a round-hand copy telling us that "familiarity breeds contempt," we can give only a qualified assent to it. There are certain things that occur annually and seem to be more pleasing each time. It is so with our present task. For many years we have been accustomed to take a review of the past year as it bears on our favourite pursuit. We can imagine how many, on reading our words, will participate in our feelings when we say the paramount is gratitude that we have been spared again to the end of another year.

Our task is easier than it was of old. The subject is more generally understood. Improvements have been suggested and carried out, and the capabilities of every breed of fowls, &c., tested to the utmost. To those who, like ourselves, have watched the progress of the pursuit, it has often been matter of surprise to see with what facility the requirements of judges have been met. It has seemed merely a question of time. We are not yet, however, so far advanced in manufacturing colour as our German neighbours. Some years ago a man offered to make any bird (Pigeon) we liked in three years; we had one coloured in the most grotesque style and sent it. We had the fac-simile alive within three years. This has been done in England in poultry. We can get anything to a feather, but we do not yet find we advance much in providing a larger amount of food; neither is there as great an advance in the quality of the poultry offered for sale as there is in the beauty of shape and plumage for exhibition. The number of shows proves the great interest still taken in the pursuit, and shows how deep-seated is the love of natural history in most minds. The prices still realised for good birds prove that the friendly competition of a show is popular. We must, however, believe that there is another future for poultry, and that it must supply more and better food than it yet does. Poultry should not remain the luxury it is, nor should it be impossible to get a really good fowl in a country town. The principal cost of rearing and fattening it is not in outlay but in labour. It will not pay to hire to do that which may be done by ourselves. We are not about to say that everyone should breed and fatten poultry, but we do say that where anyone is disposed to pay personal attention to the subject, especially in the matter of feeding, poultry will pay its own expenses if it does not leave a profit.

Our old friends the Cochins have shown still with what facility the Eastern breeds acclimatise. The same may be said of the Brahmas and the French breeds: they not only adapt themselves to our climate but they improve both in size and constitution. Those who have noticed our latest novelties in the shape of Houdans and Crève-Cœur must have remarked the great increase of size. There is ebb and flow in poultry as in all other things. Some years ago the Spanish was one of the principal classes, and many can recollect a celebrated show where two pens were sold for £300, and single birds commonly

made £20 each. Now they are as good as ever, but they make only a moderate class. The Silver-pencilled Hamburgs again have fallen both in numbers and quality till they have become a small class. The Golden do not require the same mention, but they do not hold the position they did. Their quality, however, has not suffered. Dorkings have fallen off in numbers at the great shows. They have held their own in other respects. After an absence of many years the Black Cochins have reappeared in tolerable numbers. Bantams have visibly decreased during the past year. Even at the largest shows the Sebrights cut but a poor figure, and the Game are less numerous. Had the old spirit been alive the pretty little Cochins would not have been allowed to die out. A pen of them now would make a large sum. The Rouen Ducks have in every way distanced the Aylesburys. Malays have looked up during the past year. Turkeys have made progress, not, perhaps, in the weights of the prize pens, but taken as classes they have been heavier. A recent introduction—the class for ornamental waterfowl—has exhibited not only beautiful but rare specimens. The lately rare Carolina and Mandarin Ducks are now shown in classes. The varied Whistling Ducks, the Bahama Teal, and even the Bar-headed Geese, have been seen quietly viewing the hundreds of spectators who stayed to look at them or who passed them by.

Pigeons have increased in popularity. They have always been pets, but never so generally so as at the present time. Many years ago, perhaps nearly half a century, we were struck with the Pigeons in our German Noah's Ark—many coloured; some with coloured wings and white bodies, and some just the reverse. As we stood them in a row, resting on two stumps and their tails, it was often remarked by our seniors, who were "o' the fancy," that the Germans allowed their children to colour them to their fancy, for such birds had never existed. We now have every bird and in any numbers.

We have warmed on our subject and have gone on writing just as if we were talking to one of our numerous friends. We have much pleasure in it. We have prospered and do prosper, and we like to believe we have only friends for subscribers, readers, and contributors. We are thankful we have nothing to disavow; and while we look with pride on the years of public favour we have enjoyed, we still believe we move with the age, and it is our purpose to do so.

We cannot believe that, during this year of 1875, we have caused pain to anyone. We are sorry if we have, for we have not done it willingly.

We seek to do impartially and aright, and to all with whom we have to do, and whom we thank, we heartily wish

A HAPPY NEW YEAR.

### TUNBRIDGE WELLS POULTRY SHOW.

THIS Exhibition was held on the 17th, 18th, and 20th inst. The entries were fair and the quality good, but there were several other shows held on the same days in other parts of the country, which must have damaged the entries here. The great drawback, however, was the detention of the birds over Sunday. We know for a fact that two of the greatest exhibitors in the neighbourhood refused to countenance this Sunday business, and would not send a feather. We really think they did well, for there can be no occasion for a country show to have a Sunday included at all; and really the late lamentable going-on at another Kentish show held a few days ago where the birds were kept over the Sunday—when specimens were changed and birds got out—will make exhibitors nervous, we hope, of entering at them. We really do wonder they can countenance the fact, for there is no doubt exhibitors have it in their power, by not supporting such exhibitions, to stop the practice. Mr. Leno and Mr. Martin judged the poultry, and their awards were satisfactory. Mr. P. H. Jones awarded the Pigeon prizes, except in the Homers where Mr. Cotton adjudicated, both also satisfactorily.

Dorkings were good, but not up to the standard of the last Show. The cup went to a grand pair of Coloured birds. We did not care for the way this variety was classified, as it gave no chance to the Whites and Silvers against the Coloured, which could be entered in every class. Cochins were a nice lot, the Buffs really admirable. The cup went to a fine pair of Buffs in beautiful feather and of much quality. Second and third were good birds, well-coloured and large. In the next class a fine pair of Whites were first; we liked the hen very much. In the next class Lady Gwydyr's bird was a splendid fellow. Beyond the prize birds there was not much else up to the mark in this class. Brahmas were very good in quality and quantity; they did ample justice to the good fare provided for them and came in goodly numbers. The cup went to Cresting for a grand old cock, monstrous, deep and good in colour. In hens Mr. Ansdell's old hen looked very well; adult Lights were nice, and we are glad to see Mr. Scott winning again with his old loves. Dark Brahma cockerels were very good, the winners really excellent; while the Lights made two large classes of much merit, the cup going to an admirable pullet. The noticed birds too

they were a better match. Jacobins, Turbans, and Trampcoats were not very numerous nor the quality first-rate. English

There was nothing of note adequate outside the first class.  
**Pigeons.**—Here we were glad to note an improvement in the classification of the Pouters, and a consequently more numerous country as well as a great advance in quality. Pouter cocks had eleven exhibits: first a grand bird of a bad colour (Red); second also Red, but though a good one also deficient in that point; they were however undoubtedly the best birds. Third wanted fair Mealy. Pouter hens were headed by a nice Black, which was also won the special for best bird in the first five classes. Second stylish Blue, third Black. Young Pouters numbered eight; first was a good Red hen, a stylish bird with a nice pair of legs; second White (cock) with as good a pair of well-set-on legs as any Pouter in the Show. Carriers were not very numerous, but we certainly liked the second, a grand Black hen far before the first, a bad-coloured Dun cock, but we understand the Judges thought the former a cock also. Barbs were, except the first, only middling; there however were really good Yellows. Tumblers, first Kites and we think two hens; second, Red Agates, the cock vary wry-beaked; third, Almonds, a good pair, well-coloured cock, hen bad in that respect, but both good heads. Highly commended were nice Yellow Agates. Common Tumblers were fair; third was best had they been in order, but one bird was very ill. Fantails were, except two pens, bad; first were nice pair but not up to the third, though we must confess they were a better match. Jacobins, Turbans, and Trumpeters were not very numerous nor the quality first-rate. English

SIX NEWBORN CAMELIDS—1 and 2, G. & J. Mackley. 3 and 4, Captin and Fairbairn. 5, J. Yallop. J. Adams. 6, E. W. Latham.  
SIX LIZARD CAMELIDS—1 and 2, Captin & Fairbairn. 3, E. B. Newcom. 4, J. Adams. 5, J. Yallop. 6, E. W. Latham.  
GOLDFISH MULES—1 and 2, G. & J. Mackley. 3, E. W. Latham. 4, J. A. Adams. 5, J. Adams. 6, J. Yallop. W. Evans.

Owls were the reverse, being extra fine. Nuns and Magpies were good; while in the Variety first went to Foreign Owls, second to Archangels, and third to Ice. We published the awards last week.

### BELFAST SHOW OF POULTRY, &c.

THE North of Ireland Ornithological Society's Show was held in the Ulster Hall on the 15th and 16th inst. This place is well chosen for the purpose, and the Show was well managed by a staff of thorough fanciers. The entries were in advance of those of last year, and the quality was good in all the sections. The pens were supplied by Messrs. Turner of Sheffield.

**Dorkings** headed the list, and these, and most others, were shown singly, the Dark Greys being very good, as also the Silvers, the cocks being especially good. In Buff Cocks the winners were some grand birds; the winners were of this year. Hens were even better, and very uniform in quality. In cocks the cup was won by the Buff priced at £5 in the catalogue; and in hens a grand old White was awarded the piece of plate. Partridge cocks were very good. Dark *Brahma* cocks were very good; but of the rest both Dark and Light little can be said, the Lights being positively poor. In *Spanish* were some good birds, the first-and-cup cockerel one of the best seen this season; second also good; third an aged bird. In hens a most extraordinary bird was placed first; the second a grand pullet. *Game* were not numerous, but the winners good, the cup going to a capital Pile cock. *Houdans* were a fair lot; the *La Flèche* very fine, and won the cup. In *Hamburgs* the Golden-pencils and Spangles were much better than the Silvers, the cup going to a most perfect pen of Pencils, closely pressed by another pen of that variety. These were all in pairs, as also the French and all the Bantams. *Game Bantams* were poor except the winners, the Blacks being extremely good—better, in fact, than any we have seen this year. In the Variety *Sebrights* were the winners. *Malays* were very good, and the *Polands* also. In the Variety class the Black Hamburgs and Guinea Fowls were the winners. Both the Selling classes were very large, and there were some good cheap birds. The *Rouen Ducks* were a fine lot, but the *Aylesburys* not so good. In the Variety class first were *Mandarins*, second *Spotted Bills*, and third *Carolinians*.

**Pigeons** were a grand display, and were placed in a separate part of the Hall. The show of Pouters and Carriers being one of the best seen this season, the members' classes contributing birds of high quality, and in many of the standard classes almost every bird was noticed. The *Short-faced Tumblers* and *Barbs* were not numerous, and the *Red Jacobins* not as good as we expected to find; but the *Yellow*, *Black*, and *White Jacobins* were most splendid classes, among which it would be almost difficult to particularise. *Trumpeters* were very good, the combination of feet-feathering with rose and crest, so long desired, seem to be on the point of attainment. There were some very good *Fantails*, the *Blues* being uncommonly good for that colour. *Owls*, *English*, were very good, and the winners *Blue*. *Turbits* of both classes were really good, a Silver winning the cup. The *Nuns* were perfect. *Dragoons* and *Antwerps* very good also, and well placed. There were some heavy Selling classes, with the quality of which we were not particularly struck, though many pens sold very well.

**DORKINGS.**—Coloured, except Silver-Gray.—Cock.—1, Cup, and 2, J. Walker. 2, W. G. Mulligan. *he*, W. H. King. W. H. Crabtree. *c*, Rev. S. A. Brennan. *hen*.—1, J. Walker. 2, W. H. Crabtree. 3, J. Hollway. *he* and *he*, W. G. Mulligan. *c*, W. H. King.

**DORKINGS.**—Silver-Gray or White.—Cock.—1, W. G. Mulligan. 2, J. Stevenson. 3, W. H. King. *c*, Miss De Courcy Drevier. *hen*.—1 and Cup, J. Walker. 2, W. H. King. 3, J. Stevenson. *he*, W. G. Mulligan. *c*, Miss De Courcy Drevier, W. G. Mulligan.

**COCHINS.**—Buff or Cinnamon.—Cock.—1, Cup, and 2, M. Mahoney. 3, W. G. Mulligan. *he*, W. H. Crabtree. *he*, Mrs. Pollock. *hen*.—1, F. Robertson. 2 and 3, W. G. Mulligan. *he*, W. G. Mulligan. M. Mahoney (3), Mrs. Hutchinsan, Capt. Sullivan, W. H. Crabtree. *c*, D. Sullivan.

**COCHINS.**—Any other variety.—Cock.—1, W. H. Crabtree. 2, W. G. Mulligan. 3, Dr. Stoney. *he*, W. G. Mulligan (3), M. Mahoney. *c*, W. Shaw. E. P. Williams. *hen*.—1, Cup, and 2, W. Whitworth. 3, M. Mahoney. *he*, W. G. Mulligan. F. Pettin.

**BRAHMAS.**—Dark.—Cock.—1, Cup, 2, 3, and *c*, W. G. Mulligan. *he*, A. Comyns, Jun. H. J. M'Brade (3), E. Bright. *hen*.—1, W. H. Crabtree. 2, W. G. Mulligan. 3, R. Niven. *c*, W. G. Mulligan (3), H. J. M'Brade.

**BRAHMAS.**—Light.—Cock.—1 and Cup, W. H. Crabtree. 2 and 3, E. T. Herdman. *hen*.—1, W. H. Crabtree. 2 and 3, T. Herdman. *c*, D. Sullivan, A. Field.

**SPANISH.**—Cock.—1, Cup, and 2, W. G. Mulligan. 3, W. Martin. *he*, J. A. and M. F. Smyth. J. Ross. *hen*.—1, J. Powell. 2, J. A. and M. F. Smyth. 3, J. Ross. *he*, *he*, and *c*, W. G. Mulligan.

**GAME.**—Black Red or Brown Red.—Cock.—1, J. F. Walton. 2, F. Robertson. 3, J. Ferguson. *hen*.—1, J. F. Walton. 2, Furness & Sudall. 3, F. Robertson. *Game.*—Any other variety.—Cock.—1 and Cup, J. F. Walton. *hen*.—1, J. F. Walton. 2, Furness & Sudall.

**HOUDANS.**—1, W. Whitworth, Jun. 2, W. Martin. 3, E. T. Herdman. *Game-Cock* and *La Flèche*.—1 and Cup, Miss L. Stephenson (La Flèche). 2, W. H. Crabtree (Crève-Cœur). 3, E. Walton. *he*, F. Watson, Jun. (Crève-Cœur). *c*, W. B. Maxwell (La Flèche). A. Carewell (Crève-Cœur).

**HAMBURGERS.**—Gold-spangled.—1, M. Beldon. 2, G. & J. Duckworth. 3 and *he*, J. Crawford. *c*, Dr. Stoney. *Silver-spangled*.—1, H. Beldon. 2, Ashton and Booth. 3, F. C. M. Smith. *c*, J. Ross.

**HAMBURGERS.**—Gold-pencilled.—1 and Cup, H. Beldon. 2, G. & J. Duckworth. 3, J. Barlow. *Silver-pencilled*.—1, H. Beldon.

**POLISH.**—1, H. Beldon. 2, J. H. Miller. 3, Miss De Courcy Drevier.

**MALAYS.**—1, 2, and 3, H. J. M'Brade. *he*, J. K. Miller. *c*, J. MacMillan.

**BANTAMS.**—Game.—1, B. Walton. 2, W. Shenton. 3, W. Martin. *c*, J. N. E.

*Pim.* Black.—1 and Cup, J. Walker. 2 and 3, R. H. Ashton. *he*, E. Walton. *he*, W. Shaw. *Any other variety*.—1 and 2, A. Robertson. 3, Miss Donnelly. *c*, J. N. E. Pim.

**ANY OTHER DISTINCT VARIETY.**—1, J. Ross (Black Hamburg). 2, H. Beldon. 3, P. Smith (Guinea Fowl). *c*, J. Girdwood (White Guinea Fowl). **SELLING CLASS.**—Cock.—1, J. Ross (Black Hamburg). 2, J. Ferguson (Black Red Game). 3, E. Macalmon (Partridge Cockerin). *he*, M. Mahony (Cockerin). F. Robertson. Furness & Sudall, W. H. Crabtree, W. Whitworth, Jun. *c*, E. T. Herdman. *he*, M. Macalmon (Partridge Cockerin and Dark Brahma). J. Arnold (Dark Brahma).

**SELLING CLASS.**—Hens or Pullets.—1, M. Mahony (Cockerin). 2, Furness and Sudall. 3, E. P. Williams (Dorkings). *he*, F. Robertson (Buff Cockerin). J. K. Miller. *he*, E. T. Herdman. F. W. Zurborst, W. B. Maxwell (Dark Brahma). *c*, W. G. Mulligan (Brahmas and Dorkings). E. T. Herdman. E. Macalmon (Partridge Cockerin). H. J. M'Brade (Buff Cockerin). W. Whitworth, Jun. *c*, W. H. Crabtree.

**DUCKS.**—*Rouen*.—1 and 2, W. G. Mulligan. 3, J. Walker. *he*, J. Girdwood. *he*, J. Girdwood. W. G. Mulligan. W. B. Maxwell. F. Robertson. J. K. Miller. *c*, W. G. Mulligan. *Aylesbury*.—2, F. Robertson. 3, W. Martin. J. Walker. *Any other variety*.—1 and 2, W. Martin. 3, J. Walker. *he*, E. P. Williams (Ruddy Shells). *he*, G. Jamieson (Black East Indians). E. P. Williams (Shells). W. Lindsay (Mandarins).

**TURKEYS.**—1, J. Walker. 2, F. Watson, Jun. 3, Rev. N. J. Ridley. *he*, J. G. Boyd.

### PIGEONS—MEMBERS' ONLY.

**POUTERS.**—Young Cuck.—1 and 2, J. Walker. Young *hen*.—1, Mrs. Ladd. 2, 3, and *c*, J. Wallace.

**CARRIERS.**—Black or Dun.—Young Cuck or *hen*.—1, 2, 3, and *he*, J. Montgomery.

**BARRAS.**—Young Cuck or *hen*.—1, 2, and 3, W. A. P. Montgomery.

### OPEN COMPETITION.

**POUTERS.**—Blue or Black-pied.—Cock.—1, Cup, and *he*, Rev. W. C. Bullen. 2 and *c*, R. Fulton. *he*, J. Wallace. *hen*.—1 and 2, Rev. W. C. Bullen. 3 and *he*, R. Fulton.

**POUTERS.**—Red or Yellow-pied.—Cock.—1 and 2, R. Fulton. 3, J. H. Hutchinson. *he*, J. Wallace. *hen*.—1 and 2, Rev. W. C. Bullen. 3 and *c*, R. Fulton.

**POUTERS.**—White.—Cock.—1, W. A. P. Montgomery. 2, J. H. Hutchinson. 3, Mrs. Ladd. *he*, R. Fulton. *c*, F. W. Zurborst, J. Wallace. *hen*.—1 and Cup, R. Fulton. 2, Rev. W. C. Bullen. 3, F. W. Zurborst. *he*, J. H. Hutchinson. F. W. Zurborst, Mrs. Ladd. *c*, Mrs. Ladd.

**CARRIERS.**—Black.—Cock.—1, *he*, and *c*, J. Montgomery. 2 and 3, R. Fulton. *hen*.—1, R. Fulton. 2 and *he*, J. Montgomery. 3, W. Lindsay. *he*, J. Montgomery (3), R. Fulton.

**CARRIERS.**—Dun.—Cock.—1, Cup, and 2, J. Montgomery. 3, R. Fulton. *hen*.—1, Cup, and 2, R. Fulton. 3, *he*, and *c*, J. Montgomery.

**TUMBLERS.**—Short-faced almond.—Cock.—1, Cup, and 2, R. Fulton. 3 and *he*, M. Stuart. *hen*.—1, 2, and 3, M. Stuart. 2 and *he*, R. Fulton.

**TUMBLERS.**—Short-faced any other colour.—Cock.—1, Cup, 2, and *c*, M. Stuart. 3 and *he*, R. Fulton. *hen*.—1, 2, and 3, M. Stuart. *he*, W. A. P. Montgomery. *c*, R. Fulton.

**WATERS.**—Cock.—1, Cup, 2, and 3, W. A. P. Montgomery. *he*, R. Fulton. *c*, F. W. Ewart. *hen*.—1, 2, 3, and *he*, W. A. P. Montgomery. *c*, F. W. Ewart. R. Fulton.

**JACOBINS.**—Red.—Cock or *hen*.—1, 2, and *he*, J. Frame. 3, E. A. Seale. *Yellow.*—Cock or *hen*.—1 and Cup, J. Pyper. 2, J. Frame. 3, E. A. Seale. *he*, J. H. Hutchinson. *Black.*—Cock or *hen*.—1, 2, 3, and *he*, J. Frame. *Any other colour.*—Cock or *hen*.—1, J. Galt. 2 and 3, J. Frame. *he*, J. Galt. J. Frame (3), A. J. Anderson. *he*, J. M. Royce. J. Frame (3), A. J. Anderson.

**JACOBINS.**—Black.—Cock or *hen*.—1, 2, and *c*, J. M. Hutchinson. 3 and *he*, K. Fulton. *Any other colour.*—Cock or *hen*.—1, Cup, 2, and *he*, J. H. Hutchinson. 3, R. Fulton.

**FANTAILS.**—White.—Cock or *hen*.—1 and 2, J. Walker. 3, J. Waters. *he*, J. F. Lovelidge. *Any other colour.*—Cock or *hen*.—1 and 2, E. A. Seale. 3, A. Robertson.

**WATERS.**—English.—Cock or *hen*.—1, R. H. Unsworth. 2, R. Woods. 3, J. Galt. *he*, F. W. Ewart. *c*, W. G. Henry.

**TUMBLERS.**—Red or Yellow.—Cock or *hen*.—1, E. A. Seale. 2, W. G. Henry. *c*, E. A. Seale. A. & R. Hutchinson. R. Fulton. *Any other colour.*—Cock or *hen*.—1 and Cup, R. Woods. 2, R. Fulton. 3, E. A. Seale. *he*, E. A. Seale. A. J. Anderson. *c*, W. S. M. Gibbin. F. Waring.

**NUNS.**—Cock or *hen*.—1 and 2, E. A. Seale. 3, T. Reid. *Dragoons.*—Black or Silver.—Cock or *hen*.—1 and 2, W. Smith. 3 and *he*, R. Woods. *he*, E. H. Unsworth. *Any other colour.*—Cock or *hen*.—1, Cup, 2, and 3, R. Woods. *he*, F. Robertson.

**ANTWERPS.**—Short-faced.—Cock or *hen*.—1 and 2, C. Gamon. *Long-faced.*—Cock or *hen*.—1 and 2, C. Gamon. 3, F. Robertson.

**FLYING TUMBLERS.**—Beards.—Cock or *hen*.—1, R. H. Unsworth. 2 and 3, T. Reid. *he*, F. Waring. T. Reid. R. Fulton. *Sails.*—Cock or *hen*.—1, T. Reid. 2 and 3, E. H. Unsworth. *he*, J. Waters. F. Robertson. *Any other colour.*—1, J. Wilson. 2, J. H. Unsworth. 3, F. Robertson. *he*, J. Waters.

**ANY OTHER VARIETY.**—Cock or *hen*.—1, W. Brown (White African). 2, E. A. Seale (Red Marple). 3, J. Waters. J. Wallace (Lace Fan) *he*, E. A. Seale (Fire Pigeon). R. Fulton (Turbiten). *he*, F. W. Zurborst. J. Wallace (Loe). *c*, J. Waters.

**SELLING CLASS.**—Cock or *hen*.—1, W. A. P. Montgomery. 2 and 3, J. M'Alpin (Carrier and Barb). *he*, F. W. Zurborst. J. Piper (Jacobin). J. M'Alpin (Jacobin). *c*, A. T. Anderson (White African Owl).

**SELLING CLASS.**—Pair.—1 and 2, W. A. P. Montgomery (Barb). 3 and *c*, J. M'Alpin (Jacobins). *he*, W. B. M'Gibbin (White African Owl). J. Pyper (Jacobins). J. M'Alpin (Jacobins).

### CAGE BIRDS.

**NORWICH.**—Clear.—*hen*.—1, W. Stitt. *NORWICH.*—Marked or Variegated.—Cock.—1, Cup, and 2, W. Stitt. *hen*.—1 and 2, W. Stitt.

**BELOANS.**—Yellow.—Cock.—1, Cup, and 2, J. S. Watson. 3 and *he*, J. Elliott. *c*, W. Stitt. *hen*.—1 and 2, W. Gault. 3, W. Stitt.

**BELOANS.**—Buff.—Cock.—1 and 2, J. Elliott. 3, W. Gault. *he* and *c*, W. Stitt. *hen*.—1 and 2, J. S. Watson. 3, W. Gault. *c*, W. Gault.

**SCOTCH.**—Yellow.—Cock.—1 and Cup, J. Tweedie. 2, D. Duncan. 3, T. Scott. *he*, J. Watson. *c*, W. Gault. *hen*.—1, J. Tweedie. 2, D. Duncan. 3, T. Scott. *he*, F. Harrington. J. A. Watson. T. Fox. *c*, J. Elliott. W. J. Thompson.

**SCOTCH.**—Buff.—Cock.—1, J. Pettigrew. 2, T. Scott. 3 and *he*, D. Duncan. *c*, J. Callaghan. *hen*.—1, J. M'Nab. 2, T. Scott. 3, J. Callaghan. *he*, W. Stitt. *c*, M'Burney.

**SCOTCH.**—Fleeced or Pied, Yellow.—Cock.—2, J. Pettigrew. 3, T. Scott. *he*, J. S. Watson. *c*, J. Callaghan. D. Duncan. *hen*.—1, J. Pettigrew. 2, J. A. Pryde. *he*, *c*, W. Callender.

**SCOTCH.**—Fleeced or Pied.—Buff.—Cock.—1, T. Scott. 2, J. Callaghan. 3, W. Callender. *he*, J. A. Pryde. *c*, E. Burns. *hen*.—1, J. Pettigrew. 2, T. Scott. 3, J. Watson. *c*, J. M'Nab.

**CANARIES.**—Any other variety.—1, 2, and 3, W. Stitt (Golden and Silver-spangled Larks).

**MULES.**—Any variety.—1, G. Jamieson. 2 and *c*, W. G. Mulligan. 3, J. Crawford.

**BRITISH SONG BIRD.**—1, E. Burns (Goldfinch). 2, G. Jamieson (Goldfinch). 3, J. M'Burney (Goldfinch).

**SELLING CLASS.**—1, W. Gault. 2, J. M'Alpin. 3, J. M'Burney. *c*, J. M'Nab. J. A. Pryde. J. M'Alpin.

**PARROTS.**—1, A. Crawford. 2, T. Smyth. 3, J. S. Watson. *he*, J. S. Watson. T. Crawford (3), J. Pyper. *c*, J. Stewart.

**JUDGES.**—Poultry: Mr. M. Leno, The Pheasantry, Dunstable;

properly placed; third we would have placed Mr. W. G. Duncan's "Virginia—1, L. T. Spence. 2, A. Crook. 3, A. Smith. 4, A. G. Duncan.

**TURKISHS.**—1 and 2, D. Brook. 3, A. Duncan. 4, L. T. Spence. 5, Coalston.  
**JACOBINS.**—1 and 2, W. & R. Davidson. 3, A. Duncan. 4, L. T. Spence. 5, R. Scott. 6, Fisher. 7, R. Davidson.  
**ANY OTHER VARIETY.**—1, Mrs. A. G. Duncan (Turbit). 2 and 3, R. J. Wilson (Turbit and Barbel). 4, L. T. Spence. 5, R. Frew (Magpie). 6, Crook. 7, R. Coalston (Owl).  
**SKILLING CLASS.**—1 and 2, T. Roger (Pouter). 3 and 4, R. Scott (Pouter). 5, G. Greave (Pouter). 6, L. Johnston (Trumpeter). 7, A. Duncan.  
**SCOTCH FANCY.**—Yellow.—Cook.—1, G. Couper. 2, Mrs. D. Kilgour. 3, R. Crawford. 4, G. Spence. Hen.—1, R. Brown. 2, D. Black. 3, G. Couper. 4, W. Paton.  
**SCOTCH FANCY.**—Buff.—Cook.—1 and 4, Mrs. D. Kilgour. 2, J. Pratt. 3, G. Spence. Hen.—1, W. Hogg. 2, W. Paton. 3, G. Couper. 4, J. Beveridge.  
**FIREBIRD FANCY.**—Yellow.—Cook.—1, W. Hogg. 2, A. Penman. 3, J. Elliot. 4, R. Curran. Hen.—1, D. Black. 2, A. Hutton. 3, G. Spence. 4, W. Paton.  
**FIREBIRD FANCY.**—Buff.—Cook.—1, I. Gillies. 2, W. Hogg. 3, D. Black. 4, J. Elliot. Hen.—1, Mrs. D. Kilgour. 2, R. Downie. 3, W. Hogg. 4, A. Adamson.  
**IRISHMAN FANCY.**—Yellow.—Cook or Hen.—1 and 2, P. Smith. 3 and 4, J. Culbert. Buff.—Cook or Hen.—1 and 2, J. Culbert. 3 and 4, P. Smith.  
**GREEN SIBB.**—Cook or Hen.—1, J. Simpson. 2, R. Curran. 3, C. Cairns. 4, J. Thomson.  
**FOUL-PLUMED.**—1, W. Hogg. 2, J. Thomson. 3, P. Gray, jun. 4, A. Adamson.  
**GOLDEN EYED.**—Buff.—Cook or Hen.—1, 2, and 4, W. Cowan. 3, W. Kirk. Yellow.—Cook or Hen.—1, 2, and 4, J. Cowan. 3, W. Kirk (3).  
**SKILLING CLASS.**—Cook or Hen.—1, J. Paul. 2 and 3, G. Couper. 4, J. Wallace.

### PARAGON POULTRY HOUSE AND RUN.

ALL poultry fanciers are aware of the importance of allowing fowls the benefit of grass runs.

In the "Paragon," the dimensions of the house are as follows:—Length, 4 feet; width, 3 feet 8 inches; height—front, 4 feet 8 inches, back, 3 feet 8 inches. A door at the side provides

at once see the difference betwixt a fine high bred-bird and an underbred coarse one of the same variety. The portrait which "WILTSIRAS RACTOR" seems to value so much will not help him. It certainly does not show the rose and mane—they cannot be separated as "WILTSIRAS RACTOR" seems to think; they are faults united like Siamese twins. If anything can be made of it I think it is the other way, but it is such an impossible sort of Jack that it is scarcely worth noticing. Just see how the lower part of the chain falls over the wings and back, and what wonderful legs and feet it has, and the way it stands upon them is more wonderful still. If superior to the others it is an ingenious way of accounting for it by supposing that the artist understood the bird better than any of the others, but I am of opinion that it is as much underdone as they are. "WILTSIRAS RACTOR" again goes off the line when he says, "Why should he not prefer Dragoons to Carriers?" which he says he does, because the question is between good and bad, or perhaps I should say different forms of the same variety. The Dragoon (?) has a standard of its own. Another departure from the subject is that he again reverts to low-out and clean-thigh birds, a matter of minor importance, and not worth introducing until other points are settled.

"WILTSIRAS RACTOR" insists much in his remarks on kindness and toleration, the drift of which I am at a loss to see. If it is a breach of those virtues to say that the Jacobin of the present day is very much inferior to what it used to be, then I must plead guilty. In this view of it, however, I have the support of several old fanciers, whose opinions are not lightly

Fig. 121.

access to the interior, which is fitted with a sliding door (removable from the outside for the purpose of cleaning), perches to roost ten or twelve fowls, and three full-sized nests, to which is fitted a contrivance peculiar to these houses, which effectually prevents the hens from fouling their nests. In the front of the house is inserted a sliding ventilator.

The dimensions of the runs are—Length, 8 feet; width, 4 feet; height, 3 feet; and they are covered with 2-inch mesh netting. The sides and ends are screwed together, and are thus rendered really firm and stable. The top opens with hinges to allow of fowls being easily placed in or removed from the run.

The "Paragon" houses and runs are constructed so as to combine extreme lightness with strength and durability. It is a fact that a boy can clean the house, and, unaided, move both it and the run into a fresh position, in less than three minutes.

A span-roof can be substituted for the one shown in the drawing at an extra cost of 15s., but it is not recommended, as it tends to increase the weight.

The "Paragon" is that mentioned on page 516 as used at Penhurst.

### THE JACOBIN.

I was much pleased to see "WILTSIRAS RACTOR's" last remarks on English Owls, as they will finish the controversy (now, I dare say, getting tiresome to some), as he there admits all I have been contending for. An English Owl, he says, was at the Crystal Palace "that in Owl points was superior to any African." I am very glad to hear it, as there can now be no reason (there never was a shadow of one) for having classes for both. Had there only been one class English Owls would have been much superior to what they are, and fit to hold their own in one class. So much for the Owl question. The Jacobin question could be as easily disposed of if we had a few birds of the true old type to place beside the so-called Jacobins of the present day. Then I am sure the ninety-nine out of the hundred, which "WILTSIRAS RACTOR" blames me for wishing to convert, would nearly all come over at once and dispose of their birds of the Baldhead type as fast as possible, as everyone with a true fancier's eye can

to be set aside, even though the ninety-nine are against us which they are just because they have not had an opportunity of comparing the two birds together. I am no slavish follower of what has gone before or what is old, merely as such, more than "WILTSIRAS RACTOR" (though age in these matters is no proof of weakness, but rather the contrary); but when I see one of our best fancy Pigeons, of which we have a well-defined standard, evidently drawn up by men of taste, going down hill, I should be unworthy of the name of a fancier if I did not attempt to do something, however little, to arrest its downward course. To talk of different types of Jacobins is simply a delusion. If the desirable properties in a bird are fully laid down no one has a right to depart from this standard and call it by the same name. If "WILTSIRAS RACTOR" will find a name for his rose-and-mane favourites I shall not find fault.—GROVER USS, *Camphill Lodge, Broughty Ferry*.

P.S.—Since writing the above I have seen in the last number of our Journal "WILTSIRAS RACTOR's" "Christmas Greeting," and a very excellent greeting it is. One remark in particular struck me as peculiarly applicable to the Owl and Jacobin discussion. He says, "That advancing by going back is often the truest advance," a remark that all may bear in mind with advantage. "WILTSIRAS RACTOR" always comes right in the end, and this discussion will not be an exception. Kindliness and toleration are very good, but truth must come before all.—G. U.

BARSTOL SHOW.—This commences to-day. The entries are deservedly large—1489 poultry, 599 Pigeons.

### EXTRACTED HONEY VERSUS COMB HONEY.

SOME time ago I urged bee-keepers who intended to exhibit honey at the Crystal Palace Show to go in for small boxes of pure honeycomb containing from 4 to 8 lbs. each, as the most profitable way of managing their apiaries; and I venture to suggest to the Committee of Management of the Apian Society that there be a distinct prize or prizes offered for the largest number of such boxes and the best filled in the schedule of next

year's prizes. I am certain, not only that a very large quantity of beautiful honeycomb could be harvested in such small boxes, but that a ready market then and there—and if not there, elsewhere—could be formed which would largely remunerate our bee-keepers, paying them far better than by means of liquid honey, as the former fetches at least three times the price of the latter. Our bee shows will fail in great measure of their object if one result therefrom be not the opening of a market for the sale of honey. Of what use is it to encourage the keeping of bees with no demand for honey, or if the price for it is so low as to make it worth nobody's while to collect it? Already in some parts of the country run honey is dear at 5d. or 6d. per lb., whereas it would rise to 1s. 6d. or 2s. 6d. if it were only guaranteed to be pure honey in the comb, purchasable in moderate quantities, and accessible to the London market.

I see that in America complaints are already made that honey in quantity, such as is extracted in the larger apiaries by the help of the "slinger," is so cheap as to be a drug in the market, so that one begins to hear there of "stopping the production of extracted honey;" and the advice is given by a writer in the current number of the "Bee-keeper's Magazine" that "to command the best prices and most ready sale honey should be stored in glass boxes capable of holding from 2 to 3 lbs. each," I should say from 3 to 5 lbs. each. Another bee-keeper referred to in the same magazine says that, in his opinion, "it is suicidal to secure surplus honey in liquid form, and that if bee-keepers were wise they would make the production of honey in small glass boxes their especial aim in the future." There is sound sense in all this. The only difficulty lies in finding the market. But methinks if we only had the honeycomb in saleable quantities the market would very speedily be found. At present grocers and other tradesmen object to buy or sell honey for no other reason than that it does not come to them in saleable form. They can sell it fast enough, as I have proved in former years; but as it comes to them in large supers or broken up in pans, and necessitates a good deal of manipulation in the division, it is found so disagreeable to manage, from the stickiness of the honey and the quantity of wasps and bees which it attracts to their shops, that very few grocers who have once been induced to admit it will give it a second year's trial. Thus our market for our best and most highly valued honey is closed against us almost everywhere. Only in large cities, as London, where bees and wasps are practically unknown, and where honey is sold in larger quantities off-hand, is such sale possible. But only let the honeycomb be offered for sale in compact little boxes which require no manipulation by the "middleman," but will pass directly into the hands of the consumer, and every grocer will be ready enough to buy of the producer.

But how about those little boxes and their management? There surely can be no difficulty here. Instead of putting one super over a hive let four or six be used at one time, each with its separate communication with the hive below, and all protected and kept warm by a large box fitting over them like a sort of square cap. In good seasons as fast as these are filled they can be taken away, and empty boxes put in their place. A collateral advantage connected with the use of these small supers is this, that whereas in one large super the queen will often spoil the whole of it by occupying a large proportion of the combs with brood, she will rarely be found to have spoiled more than one of the small boxes; because, owing to the difficulty she experiences in passing from one to the other she will mostly remain in the first she happens to visit, or at least sufficiently long to enable the bees to pre-occupy the combs in the others with honey before she makes her appearance there. In America, where honey seems to abound in far larger quantities than with us, they sometimes have in use attached to one hive from one to two dozen or more of very small boxes, just big enough to hold 2 or 3 lbs. of honeycomb. These would probably not answer in Great Britain except at rare intervals; but there can be no difficulty or doubt of success where four are used, as advocated here. Now, such boxes would hold from 4 to 6 or 8 lbs. of honeycomb, according to their size, which would be regulated by the size of the hive or colony over which they were placed.

As these little boxes would be protected by a substantial covering, they need not be made of wood thicker than half an inch, with one or two small pieces of glass let into their sides. When sold an arrangement might be made for their repurchase when empty if returned in good order.—B. & W.

### EXPERIMENTS WITH HONEY.

I PUT up six one-pound cans of beautiful linden honey, being careful to make it one homogeneous mass by stirring. It was thrown from the combs by an extractor on July 20th, and put into cans on August 1st. The cans were placed respectively as follows: One in a dark dry cellar, one each under shades of red, yellow, green and blue glass, and the sixth can in full light. On November 8th the honey in the cellar candied to a white. November 22nd to December 10th, honey under coloured shades

candied, first in the red, next in the yellow, green and blue; while the honey in full light remained transparent until January, when it soon candied after exposure to intensely cold weather. From my experience an equal temperature would preserve certain kinds of honey, while other kinds would candy under almost any circumstances. I think that candied honey, instead of being looked upon with disfavour, should be recognised as evidently pure. I hope, however, that the above experiments will lead others to follow up the light theory with beneficial results.—(*Scientific American*.)

### THE WONDERS OF A BEE HIVE.—No. 1.

BEE LIFE is full of marvels and mysteries. The longer an observing person lives amongst bees, and the more attentively he studies their history, the more readily will he admit his inability to reach the depths and summits of the wonders of a bee hive. After years of patient investigation and close observation the most successful and advanced students of bee-life can do no more than touch the skirts of the garment. Beyond the sphere or limits of man's power or penetration, there is a world of mysteries in a bee hive. An attempt to produce an exhaustive treatise on the subject would be sheer vanity or something worse. In a few letters which I intend to write for the readers of this journal, it is not my intention to go over untrdden ground, but simply to notice and indicate some interesting features of bee history somewhat familiar to advanced apirians. During the summer months, while bees were busy at work, the pages of the *Journal of Horticulture* gave much information on practical management; and now when bees are quiet at home let us have a little gossip about queens and drones, their works and ways, their haunts and homes.

If we begin with queens we shall find marvels great enough connected with their formation and production, their birth, their life, their end. For what can be more wonderful than the fact that queens are often reared from eggs which might produce working bees, and reared to perfection as queens from eggs in fourteen days, or seven days less time than is required to rear working bees from the same kind of eggs? Fancy a great number of eggs laid every day in a hive, set in common cells, meant to be nursed there and hatched perfect working bees in twenty-one days—bees possessing instincts and mechanical powers for field labour and household work, also for nursing their young, defending their homes and possessions, and for burying their dead. Well, if the queen of this hive die or be removed the bees take a few of the eggs from worker cells, place them in royal cells, or otherwise build royal cells around them, and make or convert them into perfect queen bees in seven days less time than working bees are in their cradle cells. What a marvellous transformation! Queens are larger, more beautiful (shall I say more perfect?) than working bees. The form and colour of their bodies, their instincts and traits of characters, are quite different too. Bees live nine months only; queens live four years. The immediate cause of such transformation and difference appears to be in a substance which the bees place in royal cells as food. What it is, where it is obtained, or how manufactured no one can tell.

There is perhaps too much taken for established proof in discussing this question. It is believed by most apirians and bee historians that special treatment is required in the royal cells only, and hence perfect queens. If inquiring minds seek evidence on this point they cannot find it. If any courageous and sturdy teacher were to stand out and assert that the special treatment is not given to royal infants but to common plebeians, and is applied in the way of stint and constraint to eggs and young in worker cells, who could contradict or disprove his words? That working bees are imperfect females, and queens perfect ones, nobody questions. But which is normal and which is abnormal? Is it not natural to believe that bees, like other races, produce perfect males and females without special treatment? Is it not as natural to believe that the special treatment dwarfs and cripples workers as it is that it develops the reproductive organs of queens? What a mystery surrounds this subject! How little do we know! What a field there is for future investigation! The anomaly of having perfect and imperfect females produced and producible from the same eggs puts difficulties in the way of research however honestly and laboriously pursued. All the provisional arrangements and economy of bees are natural and wonderfully perfect, though many of them are concealed from the ken of mortals.—A. PATTISON.

### HARVESTING HONEY HIVES.—No. 8.

(Continued from page 522.)

BEES, hives, labour, and materials of every description are dearer in America than here, and if it pays there to raise honey at 7d. per lb., as it evidently does, we certainly can do it here; but to do it we must advance with the times and bring into use frame hives and the extractor. With regard to the

former there are two constant objections urged—cost and damp. I do not hesitate to say both are bugbears. A substantial frame hive with floor board, super chamber, and cover all complete, which will last out two or three straw hives, may be made by any man who can use a saw and drive a nail for 6s. In the second edition of my manual of bee-keeping I have shown how this can be done, giving drawings of every piece of wood. Even this 6s. can be considerably reduced by the use of old packing cases, &c., for material. If the bees are now in straw hives they may be transferred, combs and all, to the improved dwelling in an hour's work, and the labours of the bees will soon pay for their better lodging. As an example of how much under control the bees and their belongings are in such hives, I may say that in one hour and a half, at the end of October, I made a thorough examination of eight hives, took out, examined, and returned all the combs (eighty-eight), saw the queen in every hive, and satisfied myself of their good condition for wintering, and although I worked with naked hands I do not think I was stung at all.

I do not keep my bees for pecuniary profit but for the boundless pleasure they afford me to watch their wondrous doings. Rarely does a day pass when weather permits that I do not investigate the interior of some of the hives, which I should be wholly unable to do if they were on the old system. The other day, when visiting a friend who had this summer adopted a frame hive, I naturally examined the condition of the bees which, although numerous, I soon pronounced to be broodless and queenless. By mere chance I had a deposed queen in my pocket, which I at once placed among the bees. The poor queen was too feeble to stand, but the bees seeming to grasp at the chance of their salvation crowded round, licked and fed her so that in ten minutes I had the satisfaction to see her happy at home with the well-known circle of workers round her. The acceptance of a queen on such an off-hand introduction was scarcely to be hoped for, but it was her only chance, like a desperate operation, and it was successful. The life of the colony is probably saved. Had they been in a skep their death was certain, for their condition would not have been discovered. But I am wandering from my subject, so to return. When the contents of a straw skep are broken up for the honey there is generally a quantity of brood, which too commonly is squeezed with the honey. But even suppose this is avoided, it is rarely that it escapes destruction, permitting which is about as wise as a gardener burning the seed which he will require in the spring, for this brood would produce the very bees which would live over the winter. Every young bee is worth many old bees in autumn. In a vigorous prosperous stock every bee found therein in April will have been born since September, and as in the early spring stocks are never too strong, imagine the loss to them if their autumn brood be destroyed. Where the combs are in frames we are able to select those containing honey alone, leaving the brood and bees to perform their allotted task in nature.

The question of wooden hives being damp I may dismiss by saying it is an evil I am not troubled with, and by attention to proper ventilation I am sure it need not be feared. Doubtless many stocks have perished from that cause, but so have they in straw hives, and they will again wherever negligence is allowed.

I have before me now "Gleanings in Bee Culture," an American magazine. It is, I believe, an honestly conducted serial. It contains many scores of returns from its subscribers. I open it at random, and without selection I find the following:—"Number of stocks in spring '86, three of which were queenless. Number of stocks to date, 40; surplus honey, mostly in 5 lb. boxes, 1541 lbs." "By use of extractor and plenty of empty combs got from eight stocks three new swarms and 1026 lbs. of honey." "I took out 600 lbs. and am confident I should not have got 60 lbs. of box honey." "Had fifty hives, and have sold 439 dollars worth, and can spare 100 dollars more honey." "Have 500 lbs. comb honey, and 135 gallons extracted from forty-four stocks." "Commenced with forty-two stocks, increased to seventy-five, taken 150 lbs. box honey, 8800 lbs. extracted." "The hives I extracted yielded on an average nearly 100 lbs. From three hives for box honey it is not worth weighing; some of the extracted ones gave me 160 lbs., one 70 lbs. in one week." "Five hives 1842 lbs." These statements are all signed with names and addresses, and are, I have no doubt, in the main true. The yield of honey through the extractor is more certain than in supers. In the latter the bees somehow will not work, charm we e'er so well; if their combs are emptied they must. Figures of American extractors with explanatory notes were published on page 479 and 480.—JOHN HUNTER, *Eaton Rise, Basing.*

**BEES-CULTURE IN CALIFORNIA.**—The *Los Angeles Herald* says bee-culture is spreading rapidly in California. At the present rate of increase it is estimated that there will be in four years one million stands of bees in that and the two adjoining counties, which will produce annually 100,000,000 lbs. of honey, worth

\$20,000,000, which is more than the value of the sugar and molasses crop of Louisiana, Texas, and Florida combined.

## OUR LETTER BOX.

**TRAL PITIONED NOT DISQUALIFIED (Boco).**—Nearly, if not all, the wild fowls exhibited are pitioned, and in our opinion it should be so. It is the only condition on which they can be kept. However tame they may be, there remains always a taint of the old wild blood, and when the "whew" of the birds in the air is heard every head goes up, and if they still possess the power of flight they join them. The knowledge that they cannot fly tends to reconcile them to captivity. They are not disgraced by it, and when swimming peacefully it cannot be seen whether they are full-grown or not.

**FLYING TUMBLERS AND SHORT-FACED TUMBLERS (B. J.).**—The former, as their name implies, are strong fliers; the latter are little delicate birds with no strength of wing, and only fit to be kept in a small enclosed place. Some of them can barely fly to the top of a wall. We advise you to begin with Flying Tumblers, and after you have procured a stock have another place for Short-faces, and the larger sort will do as admirable nurses and feeders for the Short-faces, who cannot bring up their own young. For further information read diligently Brent's "Pigeon Book" which you have received from us.

**WOLSTENHOLME'S PICTURES (T. S., Gadden, Baltimore).**—"The picture of the chestnut horses I painted was the property of Messrs. Truman and Hanbury. I painted all the brew-horses of London and engraved them. I also painted and engraved the print of Pigeons which I have now by me, and shall be most happy to supply any person with as many as they will give me an order for, or paint a picture of Pigeons for any gentleman who will give me a commission. I have three pictures in hand of horses, very fine creatures, and a wonderfully large Newfoundland dog.—D. WOLSTENHOLME."

**PRICKLY COMFERT (G. M.).**—The land is rich loam on stone brash. Cows like it and sheep also. I advise you to grow lucerne instead of it. You will have of lucerne three or four "cuts" per annum. Sow it in drills a foot wide, and keep the ground free from weeds.—W. F. RADOLFF.

## METEOROLOGICAL OBSERVATIONS.

## REMARKS.

22nd.—Very windy in the night, with rain before 9 A.M. Fine day and star-light evening.

23rd.—Very fine morning, and a beautiful day throughout.

24th.—Overcast at intervals, but rainless, and frequently very fine.

25th.—Rather thick early, but a fine day with bright sun, especially in the forenoon.

26th.—Damp and foggy all day, and evening.

27th.—Dark and dull; spots of rain at intervals, but no measurable amount.

28th.—Overcast throughout; very calm, and fair.

A fine week for the season, scarcely any frost; no measurable rain, little wind, and very high barometer.—G. J. SYMONS.

## COVENT GARDEN MARKET.—DECEMBER 29.

TRADE very quiet since Christmas; no sales effected.
